

Scalar Expressions

$$\left\{ \begin{array}{c} \text{scalar-expression} \\ \left[\begin{array}{c} + \\ - \end{array} \right] \left\{ \begin{array}{c} \text{factor} \\ \text{(scalar-expression)} \end{array} \right\} \\ \text{scalar-expression} \end{array} \right\}$$

This chapter covers the following topics:

- Scalar Expression
- Scalar Operator
- Factor

Scalar Expression

A *scalar-expression* consists of a factor or other scalar expressions including scalar operators.

Concerning reference priority, scalar expressions behave as follows:

- When a non-qualified variable name is specified in a scalar expression, the first approach is to resolve the variable name as column name of the referenced table.
- If no column with the specified name is available in the referenced table, Natural tries to resolve this variable as a Natural user-defined variable (host variable).

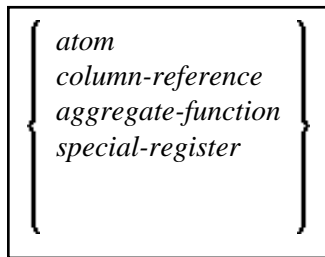

Scalar Operator

$$\left\{ \begin{array}{c} + \\ - \\ * \\ / \\ | | \\ \text{CONCAT} \end{array} \right\}$$

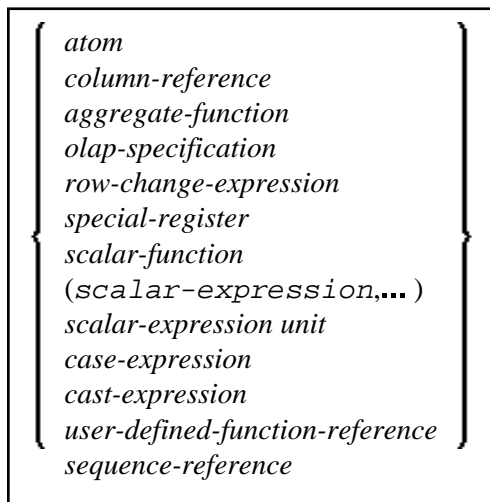

A *scalar-operator* can be any of the operators listed above; the minus (-) and slash (/) operators must be separated by at least one blank from preceding operators.

Factor

Common Set Syntax:

Extended Set Syntax:

A *factor* can consist of one of the items listed in the above diagram and described in the text below.

Atom

An *atom* can be either a *parameter* or a *constant*; see also the section *Basic Syntactical Items*.

Column Reference

A *column-reference* is a column name optionally qualified by either a *table-name* or a *correlation-name* (see also the section *Basic Syntactical Items*). Qualified names are often clearer than unqualified names and sometimes they are essential.

Note:

A table name in this context must not be qualified explicitly with an authorization identifier. Use a correlation name instead if you need a qualified table name.

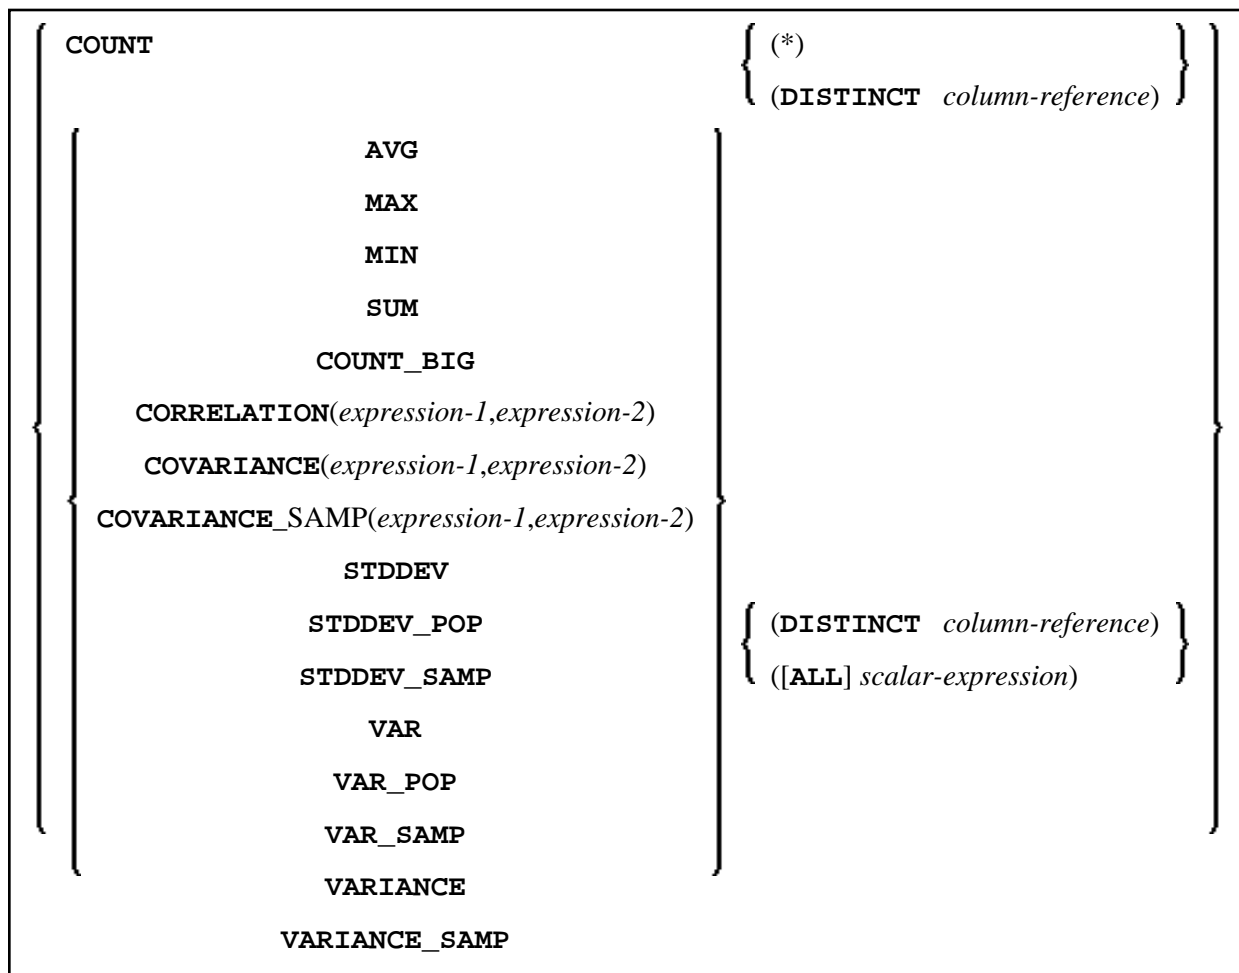

If a column is referenced by a *table-name* or *correlation-name*, it must be contained in the corresponding table. If neither a *table-name* nor a *correlation-name* is specified, the respective column must be in one of the tables specified in the FROM clause (see *Table Expression*).

Aggregate Function

Common Set Syntax:

COUNT	{ (*) }
	{ (DISTINCT <i>column-reference</i>) }
AVG	{ (DISTINCT <i>column-reference</i>) }
MAX	
MIN	
SUM	

Extended Set Syntax:

SQL provides a number of special functions to enhance its basic retrieval power. The so-called SQL aggregate functions currently available and supported by Natural are:

AVG	gives the average of the values in a column
COUNT	gives the number of values in a column
MAX	gives the highest value in a column
MIN	gives the lowest value in a column
SUM	gives the sum of the values in a column

Apart from COUNT (*), each of these functions operates on the collection of scalar values in an argument (that is, a single column or a *scalar-expression*) and produces a scalar value as its result.

Example:

```

DEFINE DATA LOCAL
1  AVGAGE      (I2)
END-DEFINE
...
SELECT AVG (AGE)
  INTO AVGAGE
  FROM SQL-PERSONNEL
  ...
    
```

In general, the argument can optionally be preceded by the keyword `DISTINCT` to eliminate redundant duplicate values before the function is applied.

If `DISTINCT` is specified, the argument must be the name of a single column; if `DISTINCT` is omitted, the argument can consist of a general *scalar-expression*.

`DISTINCT` is not allowed with the special function `COUNT (*)`, which is provided to count all rows without eliminating any duplicates.

ROW CHANGE Expression

$\text{ROW CHANGE } \left\{ \begin{array}{l} \text{TIMESTAMP} \\ \text{TOKEN} \end{array} \right\} \text{ FOR } \textit{table-designator}$
--

A `ROW CHANGE` expression returns a token or a timestamp that represents the last change to a row.

TIMESTAMP	Specifies a timestamp is returned that represents the last time when a row was changed.
TOKEN	Specifies a token of type <code>BIGINT</code> is returned that represents a relative point in the modification sequence of a row.
FOR <i>table-designator</i>	Identifies the table in which the expression is referenced. <i>table-designator</i> has to be a valid Natural SQL DDM.

OLAP Specification

$\left\{ \begin{array}{l} \textit{ordered-OLAP-specification} \\ \textit{numbering-specification} \end{array} \right\}$

ordered-OLAP-specification

$\left\{ \begin{array}{l} \text{RANK} \\ \text{DENSE_RANK} \end{array} \right\} () \text{ OVER } ([\textit{window-partition-clause}] \textit{window-order-clause})$

numbering-specification

$\text{ROW_NUMBER} () \text{ OVER } ([\textit{window-partition-clause}] [\textit{window-order-clause}])$
--

window-partition-clause

$\text{PARTITION BY } \textit{partitioning-expression}, \dots$
--

window-order-clause

ORDER BY { <i>sort-key-expression</i> <table style="display: inline-table; vertical-align: middle; border: none;"> <tr> <td style="font-size: 3em; vertical-align: middle;">{</td> <td style="padding: 5px;"> ASC NULLS LAST ASC NULLS FIRST DESC NULLS FIRST DESC NULLS LAST </td> <td style="font-size: 3em; vertical-align: middle;">}</td> </tr> </table> },...	{	ASC NULLS LAST ASC NULLS FIRST DESC NULLS FIRST DESC NULLS LAST	}
{	ASC NULLS LAST ASC NULLS FIRST DESC NULLS FIRST DESC NULLS LAST	}	

Online analytical processing (OLAP) specifications provide the ability to return ranking and row numbering information as a scalar value in the result of a query. An OLAP specification can be included in an expression, in a select-list, or in the **ORDER BY** clause of a **SELECT** statement. The query result to which the OLAP specifications are applied is the result table of the innermost subselect that includes the OLAP specifications.

RANK	Specifies that the rank of a row is defined as 1 plus the number of rows that strictly precede the row.
DENSE_RANK	Specifies that the rank of a row is defined as 1 plus the number of preceding rows that are distinct with respect to the ordering.
ROW_NUMBER	Specifies that a sequential row number is computed for the row that is defined by the ordering, starting with 1 for the first row.
PARTITION BY	Defines the partition within which the OLAP operation is applied.
ORDER BY	Defines the ordering of rows within a partition that is used to determine the value of the OLAP specification.
ASC	Specifies that the values of <i>sort-key-expression</i> are used in ascending order.
DESC	Specifies that the values of <i>sort-key-expression</i> are used in descending order.
NULLS_FIRST	Specifies that the window ordering considers null values before all non-null values in the sort order.
NULLS_LAST	Specifies that the window ordering considers null values after all non-null values in the sort order.

Example:

Display the ranking of employees that have a total salary of more than \$30,000, in order by last name.

```
SELECT EMPNO, LASTNAME, FIRSTNAME, SALARY+BONUS AS TOTAL_SALARY,
       RANK() OVER(ORDER BY SALARY+BONUS DESC) AS RANK_SALARY
FROM DSN8910-EMP WHERE SALARY+BONUS > 30000
ORDER BY LASTNAME;
```

Special Register

Common Set Syntax:

USER

Extended Set Syntax:

USER

CURRENT TIMEZONE

CURRENT DATE

CURRENT TIME

CURRENT TIMESTAMP

CURRENT SQLID

CURRENT PACKAGESET

CURRENT SERVER

CURRENT DEGREE

CURRENT RULES

CURRENT PRECISION

CURRENT OPTIMIZATION HINT

CURRENT FUNCTION PATH

CURRENT LOCALE LC_TYPE

CURRENT APPLICATION ENCODING SCHEME

CURRENT CLIENT_ACCTNG

CURRENT CLIENT_APPLNAME

CURRENT CLIENT_USERID

CURRENT CLIENT_WRKSTNNAME

CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION

CURRENT MEMBER

CURRENT PACKAGE PATH

CURRENT REFRSH AGE

CURRENT SCHEMA

CURRENT DEBUG MODE

CURRENT DECFLOAT ROUNDING MODE

CURRENT ROUTINE VERSION

A reference to a *special-register* returns a scalar value.

With the exception of `USER`, *special-registers* do not conform to standard SQL and are therefore supported by the Natural SQL Extended Set only.

Scalar Function

A *scalar-function* is a built-in function that can be used in the construction of scalar computational expressions.

For information on the scalar-functions that are supported by the Natural SQL Extended Set, see *Syntactical Items Common to Natural SQL Statements*, *scalar-function* in the *Natural for DB2* documentation.

Scalar Expression Unit

YEAR
YEARS
MONTH
MONTHS
DAY
DAYS
HOUR
HOURS
MINUTE
MINUTES
SECOND
SECONDS
MICROSECOND
MICROSECONDS

unit does not conform to standard SQL and is therefore supported by the Natural SQL Extended Set only.

Case Expression

CASE { <i>searched-when-clause</i> ... <i>simple-when-clause</i> } [ELSE { NULL <i>scalar-expression</i> }] END
--

A *case-expression* does not conform to standard SQL and is therefore supported by the Natural SQL Extended Set only.

Searched WHEN Clause

```
WHEN search-condition THEN { NULL
                             }
                             { scalar-expression }
```

A Searched WHEN clause does not conform to standard SQL and is therefore supported by the Natural SQL Extended Set only.

See details on *search-condition*.

Simple WHEN Clause

```
scalar-expression { WHEN scalar-expression THEN { NULL
                                                       }
                    } ...
```

A Simple WHEN clause does not conform to standard SQL and is therefore supported by the Natural SQL Extended Set only.

Cast Expression

```
CAST (scalar-expression AS data-type)
```

A CAST expression does not conform to standard SQL and is therefore supported by the Natural SQL Extended Set only.

User-Defined Function Reference

The option *user-defined-function-reference* belongs to the Natural SQL Extended Set. This options allows you to invoke any user-defined function. Arguments have to be placed in brackets and separated by commas. The user-defined function must be declared in the target RDBMS.

Sequence Reference

```
NEXT VALUE FOR sequence-name
PREVIOUS VALUE FOR sequence-name
```

The option *sequence-reference* belongs to the Natural SQL Extended Set.

This option allows you to reference the next value or the previous value of a sequence object. The sequence object has to be created in the target RDBMS before it could be referenced at runtime.

Scalar Fullselect

(fullselect)

The option *scalar-fullselect* belongs to the Natural SQL Extended Set.

A *scalar-fullselect* as supported in an expression is a *fullselect* - enclosed in parentheses - that returns a single row consisting of a single column value. If the *fullselect* does not return a row, the result of the expression is the null value. If more than one row is to be returned for a *scalar-fullselect*, an error occurs.
