# 1 Installation for BS2000/OSD

---

This document is intended for those who plan or perform Adabas installation for the BS2000/OSD operating system.

*Supported Environments*

*Installation Procedure*

*Installing Adabas With TP Monitors*

*Device and File Considerations*

*Installing the AOS Demo Version*

*Installing the Recovery Aid (ADARAI)*

*Adabas Dump Formatting Tool (ADAFDP)*

*ADAUTM (Universal Transaction Monitor Support)*

*Translation Tables*

Notation *vrs*, *vr*, or *v*: When used in this documentation, the notation *vrs* or *vr* stands for the relevant version of a product. For further information on product versions, see *version* in the *Glossary*.

## 2 Supported Environments

---

For information on the support platforms for this release of Adabas, read *Supported Platforms*, in the *Adabas Release Notes*.

---

# 3 Installation Procedure

This section describes the preparation for and installation of Adabas on systems running under the Fujitsu Technology Solutions BS2000 operating system.

Information for your specific installation is contained in the *BS2000 Product Installation Package* distributed with the System Installation Aid.

## Installation Checklist

The following list provides an overview of the Adabas installation procedure on BS2000 systems.

Step	Description	Additional Information
1	Provide disk space for the Adabas libraries.	The libraries are restored from the installation tape into these libraries. Refer to the section <i>Adabas Library Disk Space Requirements</i> .
2	Allocate disk space for the Adabas database.	For better performance, distribute the database files over multiple devices and channels. Refer to the section <i>Disk Space Requirements for the Database</i> .
3	Specify the address space for running the Adabas nucleus.	Refer to the section <i>Adabas Nucleus Address Space Requirements</i> .
4	Install the product license file (job I010, steps 0010 and 0011).	For more information, read <i>Installing the Adabas License File</i>
5	Allocate and format the Adabas database with the ADAFRM utility job (job I030, steps 0010 to 0018).	
6	Define the global database characteristics with the ADADEF utility job (job I030, step 0020).	
7	Start the Adabas nucleus and test the Adabas communications with the ADANUC job.	
8	Load the demonstration files ADA <i>vrs</i> .EMPL/MISC/VEHI/PERS/PERL with the ADALOD utility (performed in job I050 steps 0001 to 0003).  <b>Note:</b> The Personnel demo file must be installed on a UES-enabled database because it includes wide-character format (W) fields.	
9	If appropriate, test Adabas address space communications by running ADAREP (job I050 step 9999).	
10	If appropriate, load the Adabas Online System (AOS) selectable unit into a Natural system file by running the ADAINPL job. Alternatively, install the AOS demo version delivered with Adabas (job I061, steps 0111 and 0112).	

Step	Description	Additional Information
11	Terminate the Adabas nucleus with an ADAEND operator command.	
12	Back up the database by running the ADASAV utility job.	

## Contents of the Release Tape

The following table describes most of the libraries included on the release tape. Once you have unloaded the libraries from the tape, you can change these names as required by your site, but the following lists the names that are delivered when you purchase Adabas for BS2000 environments.

Library Name	Description
ADA <i>vrs</i> .EC <i>nn</i>	The Adabas library containing character encoding members to support various languages and Unicode. The <i>vrs</i> in the library name represents the <i>version</i> of Adabas. The <i>nn</i> letters in the library name represents a number from "00" to "99", assigned by Software AG.
ADA <i>vrs</i> .EMPL	The Employees demo file, containing dummy employee data you can use for testing Adabas. The <i>vrs</i> in the library name represents the <i>version</i> of Adabas.
ADA <i>vrs</i> .ERRN	Error messages for the Adabas Triggers and Stored Procedures Facility. These messages can be viewed using the Natural SYSERR utility. The <i>vrs</i> in the library name represents the <i>version</i> of Adabas.
ADA <i>vrs</i> .INPL	The code for Adabas Online System, Adabas Caching Facility, Triggers and Stored Procedures Facility, and various add-on demo products. The <i>vrs</i> in the library name represents the <i>version</i> of Adabas.
ADA <i>vrs</i> .JOBS	The sample job library for Adabas. The <i>vrs</i> in the library name represents the <i>version</i> of Adabas.
ADA <i>vrs</i> .MISC	The Miscellaneous demo file, containing dummy miscellaneous data you can use for testing Adabas. The <i>vrs</i> in the library name represents the <i>version</i> of Adabas.
ADA <i>vrs</i> .MOD	The load library for Adabas. The <i>vrs</i> in the library name represents the <i>version</i> of Adabas.
ADA <i>vrs</i> .PERL	The LOB demo file storing the LOB data referenced by the new Personnel demo file. The <i>vrs</i> in the library name represents the <i>version</i> of Adabas.
ADA <i>vrs</i> .PERS	The Personnel demo file, containing dummy personnel data you can use for testing Adabas. This demo file includes fields that make use of the extended and expanded features of Adabas 8, include large object (LOB) fields. The <i>vrs</i> in the library name represents the <i>version</i> of Adabas.  <b>Note:</b> The Personnel demo file must be installed on a UES-enabled database because it includes wide-character format (W) fields.
ADA <i>vrs</i> .SRC	The source library for Adabas. The <i>vrs</i> in the library name represents the <i>version</i> of Adabas.

Library Name	Description
ADA $vrs$ .VEHI	The Vehicles demo file, containing dummy vehicle data you can use for testing Adabas. The $vrs$ in the library name represents the <i>version</i> of Adabas.
APS $vrs$ .L016	A Software AG internal library. The $vrs$ in the library name represents the <i>version</i> of the internal library code, which is not necessarily the same as the version of Adabas.
APS $vrs$ .PAMS	A Software AG internal library. The $vrs$ in the library name represents the <i>version</i> of the internal library code, which is not necessarily the same as the version of Adabas.
MLC $vrs$ .JOBS	The sample job library for Software AG's common mainframe license check software. The $vrs$ in the library name represents the <i>version</i> of the license check software, which is not necessarily the same as the version of Adabas.
MLC $vrs$ .MOD	The load library for Software AG's common mainframe license check software. The $vrs$ in the library name represents the <i>version</i> of the license check software, which is not necessarily the same as the version of Adabas.
WAL $vrs$ .MOD	The load library for Adabas components shared by Adabas and other Software AG products, such as Entire Net-Work. The $vrs$ in the library name represents the <i>version</i> of Adabas.
WAL $vrs$ .SRC	The source library for Adabas components shared by Adabas and other Software AG products, such as Entire Net-Work. The $vrs$ in the library name represents the <i>version</i> of Adabas.

## Preparing to Install Adabas

---

This section provides information related to activities required prior to Adabas installation.

- [Defining a BS2000 Logon ID](#)
- [Data Sets Required for UES Support](#)
- [Adabas Library Disk Space Requirements](#)
- [Disk Space Requirements for the Database](#)
- [Adabas Nucleus Address Space Requirements](#)
- [Disk Space Requirements for Internal Product Data Sets](#)
- [Using DAB-Supported Volumes](#)

- Migrating an Existing Database

## Defining a BS2000 Logon ID

Before you install Adabas in a BS2000 system, you must:

- define a BS2000 logon ID for Adabas that permits loading from a release or installation tape;
- enable all privileges for the logon ID to allow optional operations. This includes such capabilities as priority, T/P class, and maximum virtual memory size.

When allocating direct access files, private volumes are preferred to avoid the space fragmentation that can occur with public volumes.

## Data Sets Required for UES Support

The Software AG internal product libraries (APS - operating system layer) are required if you intend to enable a database for universal encoding service (UES) support. For UES support, the following library must be loaded and included in the BLSLIB concatenation: `APSvrs.LIB` (internal product application server), updated with the last patch level (`APSvrs.Lnnn`).

**Note:** Newer APS module libraries are updates of the original. We advise you to copy the original, merge the new library into it, and reference the merged library in your JCL. The new merged library must be provided twice, with the link-name `APSLIB` and with the link-name `BLSLIB`.

Also for UES support, the following library must be loaded and included with the link name `DDEC SOJ` in the session execution JCL: `ADAvrs.EC00`, where *vrs* is the *version* of Adabas (for example, "812").

## Adabas Library Disk Space Requirements

The Adabas files and libraries require the following disk space in PAM pages where *vrs* is the Adabas *version*:

File Name	Size	Description
<code>ADA<sub>vrs</sub>.MOD</code>	1728	Module library
<code>ADA<sub>vrs</sub>.SRC</code>	480	Adabas source, macros, and example jobs
<code>WAL<sub>vrs</sub>.SRC</code>	288	Adabas limited source, macros, and example jobs
<code>WAL<sub>vrs</sub>.MOD</code>	384	BS2000-dependent modules for Adabas limited
<code>ADA<sub>vrs</sub>.EC<sub>nn</sub></code>	14532	UES code pages

## Disk Space Requirements for the Database

The Adabas database size is based on user requirements. For more information, refer to the *Adabas DBA Tasks* documentation. The following are suggested 2002 device cylinder and PAM page sizes for an initial Adabas database, allowing for limited loading of user files and the installation of Natural:

Database Component	Cylinders	PAM Pages
ASSOR1 (Associator)	50	7700
DATAR1 (Data Storage)	250	38000
WORKR1 (Work space)	50	7700
TEMPR1 (temporary work space)	25	3850
SORTR1 (sort work space)	25	3850

## Adabas Nucleus Address Space Requirements

The typical Adabas nucleus requires at least 800-1024 KB of storage to operate. The size of the nucleus partition address space may have to be larger, depending on the ADARUN parameter settings. The address space parameters for the BS2000 user ID's JOIN entry must also be adequate. Parameter settings are determined by the user.

## Disk Space Requirements for Internal Product Data Sets

The minimum disk space requirements on the disk for the internal product libraries delivered with Adabas Version 8.1 are as follows:

Library	PAM Pages
ADA $vrs$ .ECnn	14532
APS272.LIB	2304

## Using DAB-Supported Volumes

The following restrictions apply to Adabas components when located on DAB-supported volumes:

Component	Recommendations/Restrictions
ASSO	not recommended for read caching; prohibited for write caching
DATA	not recommended for read caching; prohibited for write caching
WORK	no restrictions for read caching; prohibited for write caching
CLOG/PLOG/RLOG	no restrictions for read caching; prohibited for write caching
SORT/TEMP	no restrictions
Sequential input	no restrictions

---

Component	Recommendations/Restrictions
Sequential output	no restrictions

## Migrating an Existing Database

Use the ADACNV utility to migrate existing databases to new releases of Adabas. See *Adabas Utilities* for more information.

## Installing the Adabas Release Tape

---

Adabas release tapes available to Software AG affiliates contain all Adabas product options. The affiliates use these release tapes to create custom installation tapes for customers according to contract agreements.

For specific information about your particular release tape, refer to the *Installation Notes* delivered with the installation tape.

- [Installation Using SMA](#)
- [Installation Not Using SMA](#)

### Installation Using SMA

If you are installing Adabas using the Software AG System Maintenance Aid (SMA), refer to the *System Maintenance Aid* documentation and to the information provided with the installation tape for specific installation instructions.

### Installation Not Using SMA

If you are not using SMA, copy the data sets from tape to disk using the procedure described below:

- [Step 1: Copy the Library SRVnnn.LIB from Tape to Disk](#)
- [Step 2: Copy the Procedure COPY.PROC from Tape to Disk](#)

- [Step 3: Copy all Product Files from Tape to Disk](#)

### Step 1: Copy the Library SRVnnn.LIB from Tape to Disk

**Note:** This step is not necessary if you have already copied the library SRVnnn.LIB from another Software AG tape. For more information, refer to the element #READ-ME in this library.

The library SRVnnn.LIB is stored on the tape as the sequential file SRVnnn.LIBS containing LMS commands. The current version *nnn* can be obtained from the *Report of Tape Creation*. To convert this sequential file into an LMS library, execute the following commands:

```
/IMPORT-FILE SUPPORT=*TAPE(FILE-NAME=SRVnnn.LIBS, -
/ VOLUME=<volser>, DEV-TYPE=<tape-device>)
/ADD-FILE-LINK LINK-NAME=EDTSAM, FILE-NAME=SRVnnn.LIBS, -
/ SUPPORT=*TAPE(FILE-SEQ=3), ACC-METH=*BY-CAT, -
/ BUF-LEN=*BY-CAT, REC-FORM=*BY-CAT, REC-SIZE=*BY-CAT
/START-EDT
@READ '/'
@SYSTEM 'REMOVE-FILE-LINK EDTSAM'
@SYSTEM 'EXPORT-FILE FILE-NAME=SRVnnn.LIBS'
@WRITE 'SRVnnn.LIBS'
@HALT
/ASS-SYSDTA SRVnnn.LIBS
/MOD-JOB-SW ON=1
/START-PROG $LMS
/MOD-JOB-SW OFF=1
/ASS-SYSDTA *PRIMARY

<tape-device> = device type of the tape, for example, TAPE-C4
<volser> = VOLSER of tape (see Report of Tape Creation)
```

### Step 2: Copy the Procedure COPY.PROC from Tape to Disk

Call the procedure P.COPYTAPE in the library SRVnnn.LIB to copy the procedure COPY.PROC to disk:

```
/CALL-PROCEDURE (SRVnnn.LIB,P.COPYTAPE), -
/ (VSNT=<volser>, DEVT=<tape-device>)
```

If you use a TAPE-C4 device, you can omit the parameter DEVT.

### Step 3: Copy all Product Files from Tape to Disk

Enter the procedure COPY.PROC to copy all Software AG product files from tape to disk:

```
/ENTER-PROCEDURE COPY.PROC, DEVT=<tape-device>
```

If you use a TAPE-C4 device, you can omit the parameter DEVT. The results of this procedure are written to the file L.REPORT.SRV.

## Installing the Adabas License File

The product license file is supplied on the individual customer installation tape or separately via an e-mail attachment. If the license file is provided on an installation tape, you can follow the instructions in this step to install the license file. If the license file is supplied via an e-mail attachment, you must first transfer the license to your BS2000, as described in *Transferring a License File from PC to a BS2000 Host Using FTP*, in *Adabas Operations Manual* and then you can install it, as described in this step.

### ▶ To install the product license file once it has been transferred:

- 1 Run the LICMAKE license conversion job to load the license file into a library and assemble it.
- 2 Store the assembler output module ADALIC(R) in the job library and add this to your BLSLIB concatenation.

**Note:** The Adabas 81 nucleus needs a license file to start up. Either the license file is assembled as an object by ADALIC(R) into a library in the DDLIB/BLSLIB chain or the license is read from the link name DDLIC. If neither of these is the case, the nucleus will end with a DMS0A4F error because it cannot find a link name on DDLIC.

## Considerations of Device Types

The new default device type is 2002. All devices have standard block sizes that are a multiple of 4. Thus they can be used on NK4 disks.

If you do not wish to migrate the default device used by prior releases of Adabas (device 2000) to the new default (device 2002), then the JCL will need to include `DEVICE=2000` in the ADARUN cards.

### Devices and Spanned Records

Spanned record files are those loaded with the ADALOD SPAN option.

Writing a record over a block boundary in such a file requires an extra 50 to 100 bytes in the Work file block. In such cases, the Work file needs to have a block size of 50 to 100 bytes larger than the Data block size.

The default device 2002 has a Data block size of 8188 bytes; the Work file block is 8192 bytes. Therefore, there are not enough spare bytes in default device 2002 to span records over blocks. Device 2202, however, has a Data block size of 16280 bytes, while the Work file block is 16380 bytes, so this device can be used.

If the default device must process spanned records, the Work file block should be formatted, for example, as a 2010 device at blocksize 16380, and the ADADEF database define should set `WORKDEV=2010`. A zap file will be made available at a later time to address this workaround.

## The Adabas BS2000 Communication Environment

---

The installation of a supervisor call (SVC) to provide a communication environment for Adabas is not required on BS2000 systems. Adabas uses the BS2000 executive services common memory pool and eventing for interprocess communication.

The router functions are implemented in the form of subroutines contained in the module ADARER. ADARER is loaded into common memory pool during nucleus initialization, and is shared by all user tasks that issue Adabas calls.

For those systems running an earlier Adabas/WAL library but that wish to run with the Version 8 environment, the Version 8 system must be started first in order to create the version 8 router(ADARER) required for this version's nucleus.

## Applying Zaps

---

Every effort has been made to make Adabas operating system independent. However, Adabas development is done in an IBM environment and corrections and changes are prepared in this environment.

As a result, corrections are applied to Adabas modules with `IMASPZAP`, which determines the syntax of any zaps. When corrections must be applied to a module library at BS2000 locations, the zaps must be revised to the LMS format. The following example shows how this can be done:

▶ **To revise a zap to LMS format:**

- 1 Assuming a zap in the following LMS format:

```

/EXEC LMS
LIB ADAvrs.MOD,BOTH
UPDR ADAEXAMP (a)
*COR ADAEXAMP,12BC,X'47B0A123'=X'4720BAEE' (b,c)
*END
END

```

where:

*a* specifies corrections to module ADAEXAMP.

*b* verifies the contents at location X'12BC'. The correction is applied only if the content of this location is X'47B0A123'.

*c* specifies a replacement value X'4720BAEE' for the location X'12BC'.

- 2 To verify the original data at location X'12BC' on the BS2000 system, perform the following:

```

/LOAD (ADAEXAMP,ADAvrs.MOD) Load module
/DISPLAY L'12BC'.(L=4) Display original content
%D C=ADAEXAMP.H'12BC'%XL4 (AID)

```

If the data displayed is different from the value given on the original VER statement, do not continue with step 3.

- 3 Run the LMS procedure.
- 4 To ensure that the last step was performed properly, perform step 2 again. This procedure should also be used for ADARUN and ADALNK zaps, described later in this section.

## Job Variable (JV) Handling

The control job variable (JV) is filled automatically if the statement

```

/DEL-JV name
/SET-JOB-STEP
/CRE-JV name
/SET-JV-LINK *ADA,name

```

—is contained in the nucleus startup job control statements. The JV layout is as follows:

Positions	Length	Representation	Contents
1 - 128	128	undefined	unused
129 - 136	8	alphanumeric	program name
137 - 140	4	numeric	user abend code
141 - 145	5	numeric	error number (parameter or utility)
146 - 150	5	numeric	Adabas response code
151 - 157	7	numeric	CPU time, program-related (sec.)
158 - 158	1	alphanumeric	blank
159 - 165	7	numeric	elapsed time, program-related (sec.)
166 - 178	13	alphanumeric	blank, reserved

## Job Switches

---

Adabas uses job switch 10. The job switch is set by ADARUN and reset if the nucleus or utility session terminates normally. It can be used for session control to indicate whether or not a termination is normal. When ADARUN is called with PROGRAM=USER, no switches are set or reset.

## Linking User Exits A and B to ADALNK

---

One or two user exits may be linked with ADALNK:

- UEXITB (pre-command) receives control before a command is passed to a target by the router 04 call.

**Note:** Special commands emanating from utilities and from Adabas Online System are marked as physical calls. These calls must be bypassed in user exits. These calls have X'04' in the first byte (TYPE field) of the command's Adabas control block (ACB). UEXITB must check this byte and return if it is set to X'04'. Be sure to reset R15 to zero on return.

- UEXITA (post-command) receives control after a command has been completely processed by a target, the router, or by ADALNK itself.

At entry to the exit(s), the registers contain the following:

Register	Content
1	Address of the UB. If the flag bit UBFINUB is reset, the contents of the halfword at Adabas + X'86' have been moved to UBLUINFO. If those contents are greater than zero, the two bytes starting at UBINFO (UB+X'40') have been set to zero. If UBFINUB is set, no changes can be made to the UB or ACB (except for ACBRSP).
13	Address of an 18-word save area
14	Return address
15	Entry point address: UEXITB or UEXITA

Any registers except register 15 that are modified by the user exits must be saved and restored; the address of a save area for this purpose is in register 13.

If at return from UEXITB register 15 contains a value other than zero, the command is not sent to the target but is returned to the caller. The user exit should have set ACBRSP to a non-zero value to indicate to the calling program that it has suppressed the command: response code 216 is reserved for this purpose.

The UEXITB exit may set the UB field UBLUINFO to any lesser value, including zero; an abend occurs if the user exit sets UBLUINFO to a greater value. The UBLUINFO length cannot be changed when any other exit is used; for example, Adabas Review.

The user information received by a UEXITA exit may have been modified; this modification may include decreasing its length, possibly to zero, by any of the ADANUC user exits.

## Enabling Universal Encoding Support (UES) for Your Adabas Nucleus

Prior to Adabas Version 7, Entire Net-Work converted all data for mainframe Adabas when necessary from ASCII to EBCDIC. Starting with Version 7, Adabas is delivered with its own data conversion capability called universal encoding support (UES). Entire Net-Work detects when it is connected to a target database that converts data and passes the data through to Adabas without converting it.

For Adabas Version 8.1, UES is enabled by default for the link routine ADALNK.

**Note:** The use of UES-enabled link routines is transparent to applications, including applications that do not require UES translation support: it is not necessary to disable UES support.

- [Load Module and Translation Tables](#)
- [Job Steps](#)

- [Calling LNKUES](#)

## Load Module and Translation Tables

No source module for ADALNK is delivered with Adabas 8.1. The module ADALNK already has the UES component, LNKUES, and the translation tables ASC2EBC and EBC2ASC bound to it.

The ADALNK module consists of ADALNK, ADAL2P and LNKUES. You can bind modified ASC2EBC or EBC2ASC translation tables to ADALNK-BASE using the job ALNKUES.

The two standard translation tables are:

- ASC2EBC: ASCII to EBCDIC translation; and
- EBC2ASC: EBCDIC to ASCII translation.

It should only be necessary to modify these translation tables in the rare case when a country-specific character other than A-Z a-z 0-9 must be used in the Additions 1 (user ID) or Additions 3 field of the control block.

The Adabas translation table pair is provided in the section [Translation Tables](#).

## Job Steps

Job library member ALNKUES is an example job of how to link ADALNK with the UES components.

## Calling LNKUES

LNKUES is called only on ADALNK requests (X'08'), (X'0C') with reply (X'10') or (X'1C') and reply (X'20') calls if the first byte of the communication ID contains X'01' and the second byte does not have the EBCDIC (X'04') bit set.

For requests, LNKUES receives control before UEXITB. For replies, LNKUES receives control after UEXITA.

- [Required Environment](#)
- [Connection Possibilities](#)

- JCL Required for UES Support

### Required Environment

The Adabas database must be UES-enabled. See *Adabas DBA Tasks* and the ADACMP and ADADEF utilities in *Adabas Utilities* for more information.

### Connection Possibilities

UES-enabled databases are connected to machines with different architectures through Software AG's internal product software (APS) or through Entire Net-Work (WCP).

Adabas SQL Gateway (ACE) clients may not be strictly EBCDIC in an environment where databases are connected through Software AG's internal product software (APS).

### JCL Required for UES Support

The nucleus job statements for a UES nucleus require the following items:

- BLSLIB access to the APS module libraries is required, so these extras statements are required:

```
/SET-FILE-LINK APSLIB,$SAG.APSvrs.LIB
/SET-FILE-LINK BLSLIBnn,$SAG.APSvrs.LIB
```

**Note:** Newer APS module libraries are updates of the original. We advise you to copy the original, merge the new library into it, and reference the merged library in the JCL.

- The job needs to contain the procedure call below to access the DDEC SOJ object library:

```
/CALL-PROCEDURE ($SAG.APSvrs.LIB,LMSLINKLIB),(LNK-NAME=BLSLIBn1)
```

---where BLSLIB $n1$  is last in the BLSLIB sequence

- The DDEC SOJ SET-FILE-LINK statement should point to the ECS encoding objects \$SAG.ADA $vrs$ .EC $nn$  library.
- No special Software AG internal product software (APS) parameters need to be set.

The setting of extra options on the START-PROGRAM statement can be done as follows:

```
/START-PROGRAM ($SAG.ADAvrs.MOD,ADARUN), -  
/ RUN-MODE=*ADVANCED(ALT-LIB=YES,LOAD-INF=*REF,UNRES=*DELAY, -  
/ MESSAGE=*ERROR)
```

- An example of Adabas session job control for UES (BS2000) is supplied in the \$SAG.ADAvrs.SRC(ADANUCU,J) library element.

**Note:** The Software AG internal product software (APS) batch system will create a subtask job with the same user attributes as the UES nucleus job. This job will be stopped automatically when the UES nucleus is stopped.

## Linking LNKUES to ADALNK for Data Conversion

---

Adabas Version 7 was delivered with the module LNKUES for Universal Encoding Support (UES). LNKUES converts data in the Adabas buffers and byte-swaps, if necessary, depending on the data architecture of the caller. In Adabas version 7, LNKUES had to be linked to ADALNK; in version 8, LNKUES is fix bound to ADALNK.

Prior to Version 7, Entire Net-work converted all data for mainframe Adabas. When Entire Net-work Version 5.5 and above detects that it is connected to a target database that converts data, it passes the data through without converting it.

LNKUES is called only on ADALNK request (X'1C') and reply (X'20') calls if the first byte of the communication ID contains X'01' and the second byte does not have the EBCDIC (X'04') bit set.

- For requests, LNKUES receives control before UEXITB
- For replies, LNKUES receives control after UEXITA

By default, two translation tables are linked into LNKUES/ADALNK:

- ASC2EBC: ASCII to EBCDIC translation; and
- EBC2ASC: EBCDIC to ASCII translation

**Note:** It should only be necessary to modify these translation tables in the rare case that some country-specific character other than "A-Z a-z 0-9" must be used in the Additions 1 (user ID) or Additions 3 field of the control block.

If you prefer to use the same translation tables that are used in Entire Net-Work:

- in ASC2EBC and EBC2ASC, change the COPY statements from UES2ASC and UES2EBC to NW2ASC and NW2EBC, respectively.
- reassemble the translation tables and relink LNKUES/ADALNK.

Both the Adabas and Entire Net-Work translation table pairs are provided in section *Translation Tables*. You may want to modify the translation tables or create your own translation table pair. Be sure to (re)assemble the translation tables and (re)link LNKUES/ADALNK.

```

/ASS-SYSDTA *SYSCMD
/STA-PROG $TSOLNK
MODULE ADALNK,LIB=USER.MOD,ELEM=ADALNK
NCAL
LINK SYMBOLS *KEEP
INCLUDE ADALNK,ADABAS.MOD
INCLUDE ASC2EBC,ADABAS.MOD
INCLUDE EBC2ASC,ADABAS.MOD
BIND
/ASS-SYSDTA *PRIM

```

The (re)linked ADALNK must be made available to Entire Net-Work. If you are calling Adabas Version 7 and you do not have the correct LNKUES/ADALNK module, Adabas produces unexpected results: response code 022, 253, etc.

## Formatting New Adabas Data Sets

The following formatting is required when creating new data sets:

Data Set	Formatting Required
ASSO	the first track plus the first 30 RABN blocks
DATA	the first two tracks
WORK	the whole data set
PLOG / CLOG / RLOG	the whole data set
SORT / TEMP	no formatting required

**Note:** Adabas version 8.1 knows the standard block sizes for the containers of a particular device type. These do not need to be included in the link statement.

### Formatting SORT and TEMP

The SORT and TEMP files can optionally be formatted. If non-formatted files are used, the following two FILE commands must be issued:

```
/CREATE-FILE ADA99.SORT,PUB()
/SET-FILE-LINK DDSORT1,ADA99.SORT,OPEN-MODE=OUTIN
```

## Starting Adabas

---

Adabas User Exit 2 for BS2000 permits two methods for specifying the /ENTER-JOB job:

- using a job variable containing the complete /ENTER-JOB job command;
- defaulting to an ENTER-JOB RES.E.xLCO startup command.

For more information, see the description of *User Exit 2* in the user exit and hyperexit documentation.

## Interpreting BS2000 Error Messages

---

When running Adabas, some BS2000 messages may indicate that a parameter is missing or is incorrect. The following are the message IDs that can occur, and their explanations in an Adabas environment:

Message	Description
D922	SAM file allocation (for example, for DDOUT1) primary and secondary allocation must be a multiple of the both standard block size (16) and of the allocation unit (3). The smallest multiple allowed is 48. The standard block size may have been changed using the ADARUN parameter QBLKSIZE. If so, the standard block size is determined by dividing the sum of the QBLKSIZE value and 2047, by 2048.
DD99	Parallel access to a PAM file (for example, DATA) was attempted, but SHARUPD=YES was omitted
DDB1	Refer to the D922 description above
DDC2	SHARUPD=YES was specified for a SAM file (for example, DDSIBA)

# 4 Installing Adabas With TP Monitors

---

- The Adabas API for BS2000 ..... 24
- Installing Adabas with Batch / TIAM ..... 32
- Installing Adabas with UTM ..... 33

This section provides information needed to install Adabas with teleprocessing (TP) monitors TIAM and UTM.

## The Adabas API for BS2000

---

The Adabas Version application programming interface (API) comprises the modules:

- ADAUSER (delivered in source)
- ADAUSER2 (delivered in source)
- ADALNK (*not* delivered in source, but the ADALNK module is comprised of the components ADALNK.ADAL2P and LNKUES and can be used for binding modified ADALNK components)
- SSFB2C (delivered in source, plus macro B2CONFIG to customize the interface)

ADALNK contains the combined functionality of all the ADALN<sub>x</sub> modules of previous Adabas versions. Software AG recommends that you link ADAUSER to the application program and use the entry point ADABAS on the API call.

For compatibility with existing applications, ADALNK contains the following entry points:

Entry Point	TP Monitor
ADALNK	Batch / TIAM
ADALNR	Batch / TIAM (reentrant)
ADALNN	UTM running Natural
ADALNU	UTM with Assembler or a 3GL language

ADALNK is reentrant. ADAUSER, which is supplied as source to allow modification, can be made reentrant if the user application provides a 4-byte anchor area.

Because ADALNK is reentrant, parameter items previously moved into ADALNK are now found in SSFB2C.

The symbol "ADABAS" is no longer in ADALNK, but in ADAUSER.

The symbol "ADALNR" is offset X'C' (decimal 12) bytes into the start of ADALNK. If fields are to be accessed in this version of ADALNK, their offsets have changed accordingly.

- [ESD Symbols Used in the Adabas API](#)
- [ADAUSER Program](#)
- [ADAUSER2](#)
- [Fixed Linking of ADALNK or ADAUSER](#)
- [Routing and Adabas Review Parameters](#)
- [Presetting Parameters in SSF2BC](#)

- ADALNK
- ADALNK Parameter Service
- Assembling ADALNK

## ESD Symbols Used in the Adabas API

The following symbols have a special meaning in the Adabas API:

Symbol	Meaning
ADAUSRID	identification area used by Natural; identifies the caller as Natural
AUTUSRID	identification area used by ADAUTM
CMSTART	identifies the batch Natural driver
KDCKB	area in UTM holding the user/task ID
KDCUTMD	identifier that the carrier is UTM
KDCUTMID	alternative identifier that the carrier is UTM

Software AG advises you not to define or write-access any of these symbols in applications that also use the Adabas API.

## ADAUSER Program

ADAUSER is a program that links the user to Adabas. It is specific to an operating system and is independent of release level and mode. It can be used in batch and in some TP environments.

Software AG recommends that you link ADAUSER to your applications because it:

- can be made reentrant;
- is small; and
- has no version-specific functions. In future versions, application link jobs will not require changes. For example, the application and its linkage will not be affected if TCP/IP is used to access the database.

ADAUSER propagates symbols to the loaded API interface, which can be used to pass user data or determine the carrier system the application is using. ADALNK does not do this. If ADALNK is to be linked, the whole API must be linked to the application.

- ADAUSER Loading ADALNK

- **ADAUUSER Loading ADARUN**

### **ADAUUSER Loading ADALNK**

The following file statement assigns a SAM/V data set for the ADALNK parameters:

```
/SET-FILE-LINK DDLNKPAR, samv-data-set
```

If the file link DDCARD is specified and the application is not running on UTM, ADAUSER loads ADARUN. This is the traditional API.

If the file link DDCARD is not present, ADAUSER loads ADALNK. In this case, the routing information (idt\_name,dbid) and the Adabas Review buffer size can be defined in the file link DDLNKPAR.

### **ADAUUSER Loading ADARUN**

If the file link DDLNKPAR is not specified, ADAUSER loads ADARUN for using prefetch and multifetch. The routing and Adabas Review buffer parameters are then to be delivered in the file link DDCARD or \*SYSDTA.

The following file statement assigns the proper Adabas module library *modlib*:

```
/SET-FILE-LINK DDLIB,modlib
```

ADAUUSER can load modules from several libraries. If the ADARUN-defined library is found in the catalog, it becomes the primary library.

On the first call to Adabas, ADAUSER loads the latest version of ADARUN. This makes the calling process release-independent. Subsequent Adabas calls bypass ADARUN.

ADARUN processes its control statements:

- If ADARUN PROGRAM=USER (the default) and ADARUN MODE=MULTI (the default), ADARUN also loads ADALNK.
- If ADARUN PROGRAM=USER (the default) and ADARUN MODE=SINGLE, ADARUN also loads ADANUC.

This makes ADAUSER mode-independent.

## ADAUSER2

ADAUSER2 is a program that allows Natural to load a COBOL module where Natural and COBOL have separate Adabas session IDs. ADAUSER2 is delivered in the ADA<sub>vrs</sub>.SRC library and must be assembled before it can be used.

### Fixed Linking of ADALNK or ADAUSER

To resolve external symbols in the application module, link the following modules to it:

- for ADALN<sub>x</sub> symbols, ADALNK-BASE, ASC2EBC, EBC2ASC, and SSFB2C
- for the ADABAS symbol, ADAUSER (note that the delivered ADAUSER is not reentrant)

If you are linking ADALNK-BASE, ASC2EBC, EBC2ASC, and SSFB2C to the application module and you need to resolve the ADABAS symbol as well, you can alternatively do one of the following:

- Insert the TSOSLNK command `RENAME` in the application link job to rename ADALNK before you include it:

```
RENAME ADALNK,ADABAS
INCLUDE ADALNK,$SAG.ADABAS.MOD
```

- To avoid changing the link job, insert the following lines behind the label ADALNU in the supplied ADALNK source in the ADA<sub>vrs</sub>.SRC library:

```
ENTRY ADABAS
```

### Routing and Adabas Review Parameters

Routing parameters are used to locate the application's target database:

```
IDTNAME=
```

If ADALNK has been linked or loaded, these parameters are found under the link name DDLNKPAR. The ADAL2P component of ADALNK (ADALNK.ADAL2P) reads the data from DDLNKPAR and holds it in SSFB2C.

If ADAUSER has been linked or loaded and

- the file link DDCARD is present, ADARUN is loaded and these parameters are read from DDCARD. This is the traditional Adabas API.
- the file link DDCARD is not present, ADALNK is loaded and these parameters are found in DDLNKPAR.

ADARUN must be loaded in order to load and install the Adabas prefetch components:

```
ADARUN PROG=USER, PREFETCH=YES
```

### Presetting Parameters in SSF2BC

Routing, Adabas Review, and some configuration information can be preset in SSFB2C using the delivered source module in `ADAvrs.SRC` and the macro `B2CONFIG` from `ADAvrs.MAC`:

SSF2BC Parameter	Description
IDTNAME=ADAXXXXX	ID table where the database runs

For example, the following presets routing to database 99 on the IDTNAME ADA00009:

```
SSF2BC CSECT
B2CONFIG DBID=99, IDTNAME=ADA00009
END
```

### ADALNK

When loaded, ADALNK attempts to read and process control statements from its parameter data set. Entries in the parameter data set appear in the following format:

```
ADALNK IDTNAME=ADA12345
```

The ADALNK control statements are delivered with the default values specified in the following discussion. Changing default settings by using zaps or by re-assembling ADARUN and ADALNK should be the *rare exception*.

**Note:** In a future version of Adabas, it will not be possible to change ADARUN and ADALNK parameters with zaps.

### ADALNK Parameters

**Note:** Do not specify ADALNK statements in ADARUN nuclei, Entire Net-Work, ADAUSER, or utility contexts. If you do, a warning message (ADAK06) is reported, the ADALNK statements are ignored, and processing continues.

Parameter Syntax	Description
DBID= { nnnnn   1 }	Sets the default database ID. The minimum value is 1; maximum value is 65535. The default is 1.
DISACLOS={ YES   NO }	Determines whether or not ADALNK is to close all communication after executing the CL command to the last connected database so that the user task can issue BS2000 WRCPT macros (not available for ADALNN, ADALNR, or ADALNU Adalinks). The default is NO.
GROUPS={ YES   NO }	Determines whether or not the communication items are valid for all logon user IDs with no restriction (NO, the default) or whether they are valid only for the logon user ID of the present task (YES). See also the ADARUN GROUPS parameter in <i>Adabas Operations</i> .
IDTNAME={ ADABAS5B ↵   ADACCCC }	Specifies the name of the ID table to be accessed. This name must be the same as the nucleus' ADARUN IDTNAME parameter, if specified, which must be 8 characters beginning with ADA. The default is ADABAS5B.
LU=nnnnnn	Sets the size of the user buffer. The default is 0.
X48={ YES   NO }	Determines whether or not X48 call processing is available to an application so that it can build its own 28-byte communication ID to identify internal Adabas resources used by a logical transaction.

### ADALNK Parameter Service

The ADALNK parameter service coordinates ADARUN, ADALNK, and SSF parameters. It comprises three modules:

- ADAL2P component of ADALNK (ADALNK.ADAL2P) contains the parameter service routines
- the ADALNK module contains the Adalink parameters
- SSF2BC contains operating system specific parameters. Most of the operating system related defaults (such as the names, scopes, and sizes of memory pools, serialization and event items) are concentrated in this module.

The parameters in the delivered SSF2BC module contain the same defaults as associated ADARUN and ADALNK parameters and can be modified with the help of the ADARUN or ADALNK parameters. In some cases, it is desirable to hide these parameters.

- [Linking ADALNK](#)
- [B2CONFIG Macro](#)
- [Parameter Priority](#)
- [ADALNK Protocol Data Set](#)

- Message Protocol

### Linking ADALNK

The ADALNK parameter service considers the SSFB2C configuration module:

- if ADALNK is loaded by ADAUSER, SSFB2C is AUTOLINKED by V-Constant. In this case, no changes are required.
- if ADALNK needs to be bound to a user program (this is not recommended), include the following statements in the TSOSLNK JCL that links ADALNK:

```

...
INCLUDE ADALNK
INCLUDE ASC2EBC
INCLUDE EBC2ASC
INCLUDE SSFB2C
or BINDER JCL :
...
INCLUDE-MODULES ELEMENT=(ADALNK,ASC2EBC,EBC2ASC,SSFB2C),-
...

```

### B2CONFIG Macro

If other *defaults* are required, the SSF configuration module can be re-assembled. The macro B2CONFIG is delivered for this purpose.

The following operands are available:

Operand Syntax	Description
ALNKPRT={ NO   YES }	Permits or inhibits the creation of the ADALNK parameter services' protocol data set.
DBID= { nnnnn   1 }	Sets the default for the ADARUN and ADALNK parameter DBID= <i>n</i> . The maximum value is 65535; the default is 1.
DISACLOS={ YES   NO }	Sets the default of the ADALNK parameter DISACLOS.
ENVNAME=ccccccc	Sets the default for the ADARUN and ADALNK parameter IDTNAME. The operand must contain exactly 8 alphanumeric characters.
ENVSCOPE= {GROUP   GLOBAL }	Sets the default for the ADARUN and ADALNK parameter GROUPS. Specify: <ul style="list-style-type: none"> <li>▪ ENVSCOPE=GROUP for ADALNK GROUPS=YES</li> <li>▪ ENVSCOPE=GLOBAL for ADALNK GROUPS=NO</li> </ul>

Operand Syntax	Description
NUMGES={ <i>nnn</i>   6000 }	Determines the maximum number of global event control blocks allowed.

### Parameter Priority

Parameter values changed by zaps take priority over the corresponding SSFB2C.

Parameter values set by ADARUN or ADALNK statements take priority over both values changed by zaps and values from SSFB2C.

Parameter values changed by zaps are not reported on the protocol data set.

### ADALNK Protocol Data Set

The ADALNK parameter service allows you to protocol its statements

- into SYSLST (ASS-SYSLST data set);
- into a data set determined by `"/SET-FILE-LINK DDPLNPRT,data-set"` (if this link name is not included in the tasks file table, the protocol is written to SYSLST); or
- nowhere. In this case, the module SSFB2C must be assembled by setting the operand `ALNKPRT=NO`.

### Message Protocol

```

ADAK04 CONFIGURATION MODULE FOUND :
ADAK04 NAME : USERCONF; ASS-DATE 960229; VERSION 0130 (see note 1)
ADAK04 ENVNAME =ADATEST1 (see note 2)
ADAK04 ENVSCOPE =GLOBAL (see note 2)
ADAK04 DBID =145 (see note 2)
ADAK04 LRVINFO =0 (see note 2)
ADAK04 DISACLOS =NO (see note 2)
ADAK04 THE FOLLOWING ADALNx PARAMETERS ARE IN USE FOR THIS RUN
ADALNK DBID=196 (see note 3)

```

#### Notes:

1. Information to identify a user-defined configuration module.
2. B2CONFIG macro parameters.
3. ADALNK parameter read from the ADALNK parameter service.
4. Values changed by zaps are not reported.

## Assembling ADALNK

No ADALNK source is delivered with Adabas 8. To customize this interface, use UEXITA and UEXITB, as described in *Other Exits Supported by Adabas*, in the *Adabas User, Hyperdescriptor, and Collation Descriptor Exits Manual*.

## Installing Adabas with Batch / TIAM

---

The Adalink used for batch and the TIAM TP monitor environment under BS2000 is ADALNK.

The ADALNK entry point is used where a single user issues only one Adabas call at a time and waits synchronously on the call to return. The last eight bytes (UID) of the communication ID are set to either

- B<sub>xxxx</sub> (batch); or
- D<sub>xxxx</sub> (TIAM)

where <sub>xxxx</sub> is the BS2000 task sequence number.

This Adalink is loaded by ADARUN to control multiuser (ADARUN MODE=MULTI) or utility sessions. The CSECT name is ADALNK.

- [ADALNK for SAPR Application Packages](#)
- [Dynamically Loading Symbols in Batch / TIAM](#)

### ADALNK for SAPR Application Packages

The ADALNR entry point is located at offset 'xC' in ADALNK, which is reentrant.

Calls to ADALNR require an eighth Adabas call parameter containing the address of this initialized area, which must be below the 16-megabyte line.

The seventh parameter, which is reserved for Natural applications, must always be defined. This parameter must always be used for each Adabas call.

The addressed area itself, which cannot be changed by the user, must equal the total of the two halfword counts found at ADALNK locations X'B4' and X'B6'.

## Dynamically Loading Symbols in Batch / TIAM

The binder/loader/starter (BLS) may be used to dynamically load the ADALN<sub>x</sub> (where *x* is K, N, Q, R, or U) or ADABAS symbol with the job statements

```
/SET-FILE-LINK DDLIB,<adabas_library>
.
/START-PROGRAM (MY.LIB,MYAPPL),RUN-MODE=ADVANCED(ALT-LIB=YES)
.
```

where *adabas\_library* is the name of the delivered Adabas module library.

If the program MYAPPL has the unresolved external symbol:

- ADALN<sub>x</sub>, then ADALNK and SSFB2C are loaded.
- ADABAS, then ADAUSER is loaded, which in turn loads ADARUN, ADAIOR, etc.

## Installing Adabas with UTM

This section provides information required for Adabas installation with UTM.

- [Operation Options](#)
- [Unsynchronized Operation](#)
- [Running ADASAV under UTM](#)
- [UTM Adalink Entry Points](#)
- [Linking ADAUSER to UTM Applications](#)

### Operation Options

UTM can operate with Adabas in two modes:

- *Synchronized.* UTM transactions and database transactions are coordinated.

UTM is aware of database transactions and coordinates its transactions with Adabas, providing automated restart in case of failure. The selectable unit ADAUTM documented in section [ADAUTM](#) is required to implement this option.

- *Unsynchronized.* The application completes database transactions independently of UTM.

UTM is not involved in the database transactions. Several Adabas transactions can occur within a single UTM transaction. Applications call Adabas from the ADALNK module directly. The following sections describe the process of selecting the correct UTM ADALN<sub>x</sub> entry point.

## Unsynchronized Operation

UTM conforms to the KDCS (compatible data communication interface) description, which requires a TP program with the following general sequence:

1. initialize
2. obtain the terminal input data
3. process the data (including any Adabas calls)
4. write the output data to the terminal
5. end (PEND).

Under UTM, a BS2000 task processes only a single user until PEND. By defining multiple UTM tasks for an application, requests are processed in parallel, thus improving performance.

Multiple tasks are also required to prevent deadlock situations. For example, if only one UTM task is available and user 2 requests a record held by user 1, all processing stops (deadlock) until user 2 is timed-out, thus freeing the UTM task to complete user 1's transaction.

## Running ADASAV under UTM

The Adabas utility ADASAV should only be run on a UTM system when very few update transactions are active, or deadlock can result. This occurs when fewer UTM tasks have been defined than can accommodate the number of Adabas user transactions currently open, and the ADASAV synchronization begins.

When ADASAV performs synchronization, all ET transactions are held in the command queue (CQ) until none remain to be processed. If there are more open UTM transactions than UTM tasks available, other transactions cannot be completed until the UTM transactions end; this results in deadlock.

All transactions remain frozen, waiting for time-out to occur. When the first time-out of a UTM transaction occurs, a UTM task is freed and another UTM transaction takes its place. This continues until all frozen transactions are freed, bringing synchronization to an end.

## UTM Adalink Entry Points

Software AG strongly recommends that you link ADAUSER to the UTM application and that you use the ADABAS entry point.

For compatibility reasons, ADALNK may be linked to a UTM application using one of the following entry points:

- ADALNN for systems running with Natural, and
- ADALNU for systems running without Natural.

Both are described as provided on the Adabas/BS2000 release tape; however, ADALNN and ADALNU defaults can be changed (zapped). While the Adabas call is being processed, the UTM task waits synchronously until the Adabas nucleus returns the call results.

## ADALNN

ADALNN is used where the calling program works with different users, or must identify more than one transaction. However, only one Adabas call is processed at a time, and waits are synchronous. ADALNN is used with Natural/UTM or Natural/TIAM/MULTIPASS. The CSECT name is ADALNN. There are no additional ENTRIES.

## ADALNU

ADALNU is for UTM applications that do not run with Natural. The UID part of the communication ID is set with the logical terminal ID derived from the KB header field KCLOGTER. For UTM version 3, the KB is found by the weak external KDCKB that is satisfied in KDCROOT. For older UTM versions, or in environments where ADALNU is not linked statically to KDCROOT, ADALNU locates the KB in the program's parameter list by going back up the save area chain to the KDCROOT save area.

## Linking ADAUSER to UTM Applications

- [Natural](#)
- [COBOL or Assembler](#)
- [Loading ADALNK](#)

### Natural

Software AG recommends that you link ADAUSER to the Natural UTM application and set the Natural driver parameter.

```
ADACALL=NO
```

ADAUSER detects that UTM is the carrier system. It loads ADALNK directly and thus reads its parameters from DDLNKPAR.

### COBOL or Assembler

If ADAUSER is linked to a COBOL or Assembler UTM application, ADALNK is loaded and parameters are read from DDLNKPAR.

## Loading ADALNK

Whenever you link ADAUSER to UTM applications, you need to add the following link statement to the UTM start job to load the ADALNK:

```
/SET-FILE-LINK DDLIB,<adabas_library>
```

where *adabas\_library* is the name of the delivered Adabas module library.

# 5

## Device And File Considerations

---

- Information to be Zapped into the First Free TDCE ..... 38
- General Rules for Defining Device Block Sizes ..... 40
- BS2000 Device Types and Block Sizes ..... 42

Support for new device types that include user-defined block sizes can be implemented in Adabas by modifying one of the table of device-constant entries (TDCEs) reserved for this purpose. A TDCE is X'40' bytes long and the first free TDCE can be identified by X'0000' in its first two bytes (TDCDT).

Under BS2000, the address of the first TDCE is at offset ADAIOR+ X'34' for all versions of Adabas.

Adabas direct access data sets are always mapped to UPAM files, removing the need to consider physical device characteristics. PAM pages in a data set are addressed relative to the data set beginning.

Adabas blocks comprise one or more PAM pages. An Adabas virtual track is made up of a fixed number of blocks, and an Adabas virtual cylinder comprises a fixed number of tracks. The definition of tracks and cylinders are independent of the physical device.

There are a number of predefined virtual devices for BS2000 that should meet most of the storage capacity needs that arise. It should be noted that the virtual memory requirement increases significantly with a larger block size.

Support for new device types, including user-defined block sizes, can be implemented in ADAIOR by modifying one of the TDCEs reserved for this purpose.

**Note:** The default device type for BS2000 in Adabas 8 is 2002. This device type is compatible with NK4 disks, whereas the old default device type of 2000 does not.

## Information to be Zapped into the First Free TDCE

---

The information in the following tables must be zapped into the first free TDCE. The rules described in the section *General Rules for Defining Device Block Sizes* must be followed when changing the TDCE.

Label	Offset	Contents
TDCDT	00	Device type in unsigned decimal (X'3385'), must be numeric, and unique among all TDCEs
TDCKSN	02	Constant set number: must be uniquely chosen from the values X'28' (reserved for BS2000 device type 2006), X'2B', or X'2E'
TDCF	03	The flag bit must be set—TDCFFBA (X'80') for FBA/PAM devices or TDCFCKD (X'40') for CKD devices
TDCDT1	04	Set to zero under BS2000
TDCDT2	05	Set to zero under BS2000
TDCDT3	06	Set to zero under BS2000
TDCDT4	07	Set to zero under BS2000

Label	Offset	Contents
TDCMSBS	08	In BS2000, 32760 for compatibility. Refer to the TDCMSBS default table in <i>Maximum Sequential Block Size</i> in the Adabas z/OS installation instructions for more system- and device-related information.
TDCTPC	0A	Number of tracks per cylinder
TDCCIPT	0C	Number of FBA blocks or PAM pages per track (if TDCFFBA is set). For BS2000 less than or equal to 16.
TDCBPCI	0E	Number of bytes per FBA block or PAM page (2048 if TDCFFBA is set)
TDCABPT	10	Number of Associator blocks per track
TDCABS	12	Associator block size
TDCACPB	14	Number of FBA blocks or PAM pages per Associator block (if TDCFFBA is set)
TDCDBPT	16	Number of Data Storage blocks per track
TDCDBS	18	Data Storage block size
TDCDCPB	1A	Number of FBA blocks or PAM pages per Data Storage block (if TDCFFBA is set)
TDCWBPT	1C	Number of Work blocks per track
TDCWBS	1E	Work block size
TDCWCPB	20	Number of FBA blocks or PAM pages per Work block (if TDCFFBA is set)
TDCTSBPT	22	Number of TEMP or SORT blocks per track (if TDCFFBA is set)
TDCTSBS	24	TEMP or SORT block size
TDCTSCPB	26	Number of FBA blocks or PAM pages per TEMP or SORT block (if TDCFFBA is set)
TDCPBPT	28	Number of PLOG blocks per track
TDCPBS	2A	PLOG block size
TDCPCPB	2C	Number of FBA blocks or PAM pages per PLOG block (if TDCFFBA is set)
TDCCBPT	2E	Number of CLOG blocks per track
TDCCBS	30	CLOG block size
TDCCCPB2	32	Number of FBA blocks or PAM pages per CLOG block (if TDCFFBA is set)

In addition, the length of a sequential protection log block may have to be increased. This length is contained in the corresponding PTT entry in CSECT ADAIOI of the load module ADAIOI. The address of the first PTT entry is contained in the fullword at ADAIOR+X'518'.

Each PTT entry is X'10' bytes long and has the structure shown below:

Label	Offset	Contents
PTTPN	00	Program number
PTTFT	01	File type
PTTN	02	DD name characters 2 - 8

Label	Offset	Contents
PTTF	08	Flags: OUT (X'80') output BSAM (X'40') BSAM BACK (X'20') read backwards JCL (X'10') BLKSIZE/LRECL/RECFM taken from DATADEF statement or label UNDEF (X'04') undefined record format VAR (X'02') variable record format
-	09	Reserved
PTTMBS	0A	Maximum block size
-	0C	Reserved

The PTT entry for the sequential protection log can be identified by X'12F1' in its first two bytes.

## General Rules for Defining Device Block Sizes

The following general rules must be followed when defining Adabas device block sizes:

- all block sizes must be multiples of the number of PAM blocks per track (see *Device Types and Block Sizes*, elsewhere in this section)
- a single block cannot be split between tracks (block size must be less than or equal to the track size)

### Block Rules for ASSO/DATA

The following rules apply for Associator and Data Storage blocks:

- Associator block size must be greater than one-fourth the size of the largest FDT, and should be large enough to accept definitions in the various administrative blocks (RABN 1 - 30) and in the FCB
- The block sizes for Associator and Data Storage should be a multiple of 256, less four bytes (for example, 1020) to save Adabas buffer pool space
- The Associator and Data Storage block sizes must be at least 32 less than the sequential block size
- Data Storage block size must be greater than: (maximum compressed record length + 10 + padding bytes)

## Block Rule for WORK

The Work block size must be greater than either (maximum compressed record length + 110) or (Associator block size + 110), whichever is greater.

## Block Rules for TEMP/SORT

If ADAM direct addressing is used:

```
size > (maximum compressed record length + ADAM record length + 24);
size > 277 (maximum descriptor length + 24)
```

However, TEMP and SORT are generally read and written sequentially; therefore, the larger the TEMP/SORT block size, the better.

Block size for TEMP and SORT must be greater than the block size for Data Storage.

## Block Rule for PLOG or SIBA

The following rules apply for PLOG or SIBA blocks:

- The PLOG or SIBA block size must be greater than either (maximum compressed record length + 110) or (Associator block size + 110), whichever is greater.
- It is also recommended that PLOG/SIBA be defined larger than the largest Data Storage block size. This avoids increased I/O caused by splitting Data Storage blocks during online ADASAV operations.

The block size (BLKSIZE) of a sequential file is determined as follows:

```
if PTF(JCL) then BLKSIZE is taken from file assignment statement or label;
if PTTMBS > 0 then BLKSIZE = PTTMBS;
if PTTMBS = 0 then
if tape then BLKSIZE = 32760;
else BLKSIZE = TDCMSBS;
else if BLKSIZE in file assignment statement or label then use it;
if PTF(OUT) then
if QBLKSIZE > 0 then BLKSIZE = QBLKSIZE;
if tape then BLKSIZE = 32760;
else BLKSIZE = TDCMSBS;
else error.
```

**Note:** QBLKSIZE is an ADARUN parameter.

## Using 3480/3490 Tape Cartridge Compression (IDRC)

The use of hardware compression (IDRC) is not recommended for protection log files.

## BS2000 Device Types and Block Sizes

The primary access method for direct access data sets used by Adabas under BS2000 is PAM (primary access method). The device types defined by Adabas establish a logical structure on a PAM data set in order to process a fixed number of consecutive PAM blocks (e.g., one Adabas block consisting of two PAM blocks or one logical track consisting of four PAM blocks).

These device types are “artificial”; there is no relation to the physical devices being used. A maximum of 16 PAM blocks per track can be combined into one I/O call. For more than 16 PAM blocks per track, parameter chaining is used.

The artificial device types defined by Software AG for BS2000 systems are summarized in the following table. The ASSO, DATA, WORK, PLOG, CLOG, and TEMP/SORT/DSIM block sizes are given in RABNs per track.

Device	Trks/Cyl	PAM Blks/Trk	ASSO	DATA	WORK	PLOG	CLOG	TEMP/SORT/DSIM	Notes
2000	20	4	2048:4	4080:2	4096:2	4096:2	4096:2	4080:2	
2001	19	8	2044:8	4092:4	4096:4	4096:4	8192:2	8192:2	
2002	19	8	4092:4	8188:2	8192:2	8192:2	16384:1	16384:1	see note 1
2003	17	15	2044:15	6140:5	6144:5	6144:5	10240:3	10240:3	
2004	17	15	6140:5	10236:3	10240:3	10240:3	30720:1	30720:1	
2005	11	20	2044:20	4092:10	8192:5	8192:5	10240:4	10240:4	
2006	11	20	4092:10	8188:5	10240:4	10240:4	10240:4	10240:4	
2007	17	15	10236:3	30716:3	30720:3	30720:3	30720:3	30720:3	see note 2
2008	17	16	4092:8	32656:1	32760:1	32760:1	32760:1	32760:1	see note 1
2009	17	16	4092:8	32656:1	32740:1	32740:1	32740:1	32740:1	see note 1
2010	15	16	4092:8	8188:4	16380:2	16380:2	16380:2	16380:2	see note 1
2200	15	16	4092:8	8088:4	16380:2	16380:2	16380:2	16380:2	see note 1
2201	15	12	4092:6	12184:2	12288:2	12288:2	12288:2	12288:2	see note 1
2202	15	16	4092:8	16280:2	16380:2	16380:2	16380:2	16380:2	see note 1

### Notes:

1. This device can be used with BS2000/NK4 disk types. In these cases, all direct access database files have been defined with a standard block size which is a multiple of 2.

2. Although supported, the 2007 device is not recommended for use with Adabas. Support for the 2007 will be removed in a later Adabas release.

If the current database device is not of a compatible type for NK4 disks and it is necessary to migrate it to those disks, you must use the ADAORD RESTRUCTUREDDB utility as described in *Adabas Utilities*.

### Splitting Data Sets Across Volumes

For private volumes, splitting is possible under every LOGON user ID:

In ISP format:

```
/FILE data-set,DEVICE=D3480,VOLUME=PRIV01,SPACE=60000
/FILE data-set,DEVICE=D3480,VOLUME=PRIV02,SPACE=60000
```

In SDF format:

```
/CREATE-FILE data-set,PRIV-DISK(SPACE=(60000),VOLUME=PRIV01)
/MOD-FILE-ATTR data-set,PROT=(USER-ACC=*ALL)
/MOD-FILE-ATTR data-set,SUP=PRIV-DISK(SPACE=(60000),VOLUME=PRIV02)
```

For public volumes, the splitting is possible under every LOGON user ID if the master catalog entry of the pubset has the attribute:

```
PHYSICAL-ALLOCATION=USER-ALLOWED
```

This attribute is set by issuing the following command under TSOS:

```
/MOD-MASTER-CAT CAT-ID=ABC,PHYSICAL-ALLOCATION=USER-ALLOWED
```

Once this attribute is set, it is possible to split a data set across two or more public volumes under any LOGON user ID that has the right of space allocation on that particular pubset.

In ISP format:

```
/FILE data-set,VOLUME=ABC.00,DEVICE=D3480,SPACE=60000
/FILE data-set,VOLUME=ABC.01,DEVICE=D3480,SPACE=60000
```

In SDF format:

```
/CREATE-FILE data-set,PUB(SPACE=(60000),VOLUME=ABC.00)  
/MOD-FILE-ATTR data-set,PROT=(USER-ACC=*ALL)  
/MOD-FILE-ATTR data-set,SUP=PUB(SPACE=(60000),VOLUME=ABC.01)
```

At this point, even a particular physical allocation can be made.

In ISP format:

```
/FILE data-set,VOLUME=ABC.02,DEVICE=D3480,SPACE=(20002,60000,ABS)
```

In SDF format (following the CREATE-FILE and MOD-FILE\_ATTR...PROT specifications listed earlier):

```
/MOD-FILE-ATTR data-set,SUP=PUB(SPACE=ABSOLUTE(20002,60000),VOLUME=ABC.02)
```

The example extent covers physical PAM pages 20002 through 80001 on volume ABC.02. The required disk space must, of course, be available. If you are unsure of the available disk space, consult your system administrator.

### **Saving the Extent List of Data Sets**

The utility ADAR2E converts the extent list of given data sets into a JOB containing /CREATE-FILE commands. For more information, see the section on the ADAR2E utility in the *Adabas Utilities* documentation.

# 6 Installing The AOS Demo Version

---

- AOS Demo Installation Procedure ..... 46
- Installing AOS with Natural Security ..... 47
- Setting the AOS Demo Version Defaults ..... 47

This section describes how to install the Adabas Online System (AOS) demo version. To install AOS on systems that use Software AG's System Maintenance Aid (SMA), refer to the section of this document describing installation of Adabas in your operating environment. For information about SMA, see the *System Maintenance Aid* documentation.

**Notes:**

1. To install the full version of AOS, read the *Adabas Online System* documentation.
2. Demo versions of Adabas Vista (AVI), Adabas Fastpath (AFP), Adabas SAF Security (AAF), and Adabas Transaction Manager (ATM) are automatically installed when you install either the demo or full version of AOS.

The AOS demo version requires Natural Version 2.2.8 or above.

---

## AOS Demo Installation Procedure

---

▶ **To install the AOS demo version without the System Maintenance Aid:**

- 1 The AOSASM module must be linked to the shared portion of the Natural nucleus.
- 2 Perform a Natural INPL.

The tape containing the AOS demo version contains an INPL-formatted data set in Natural 4.1. The programs for the AOS demo version are stored in library SYSAOS.

The distributed INPL jobs (both the sample jobs and the SMA-generated jobs) that you use to load the Adabas INPL library load it in a date-sensitive manner. In other words, the load process will now check the dates of your existing INPL library and will not allow older members to overwrite members with newer dates. However, if you use your own Natural batch jobs to load the Adabas INPL library, you will need to modify them to be date-sensitive. To do this, specify the following `CMSYNIN` primary command input in your job (this setting assumes the Natural input parameters in the job are specified in comma-delimited mode, or `IM=D`):

```
B,,,,,,Y
```

The "B" setting indicates that the INPL action should load everything; the next six fields (comma-delimited) are defaults, the eighth field is specified as "Y" to indicate that dates in the INPL library should be checked, and the ninth field is not included in the specification because the default for that field will be used. For more information about Natural `CMSYNIN` input, refer to your Natural documentation.

**Note:** When migrating an Adabas 7.4 installation, this procedure does not apply. Instead, you should replace the 7.4 INPL library members with the latest Adabas 8 INPL library

members, regardless of the dates of the members, to avoid creating a library containing members from both releases.

- 3 Load the ADA error messages using the Natural utility ERRLODUS.

The error messages are stored in an ERRN-formatted data set included on the tape.

See the *Natural Utilities* documentation for information about the ERRLODUS utility.

- 4 Execute the AOS demo version by logging on to the application library SYSAOS and entering the command MENU.

## Installing AOS with Natural Security

---

Natural Security must be installed before implementing Adabas Online System Security. See the *Adabas Security* documentation for more information. For information about installing Natural Security for use with AOS Security, see the *Natural Security* documentation.

Natural Security Version 2.2.8 or above includes the ability to automatically close all open databases when the Natural command mode's LOGON function of the AOS demo version is invoked.

Use the following procedure if Natural Security is installed in your environment.

### ▶ to set-up AOS using Natural Security:

- 1 Define at least the library SYSAOS to Natural Security

Software AG recommends you define this library and any others you may define as protected.

- 2 Specify the startup program for SYSAOS as MENU

Do *not* specify a startup program name for the other libraries.

## Setting the AOS Demo Version Defaults

---

Parameters that control the operation of the AOS demo version can be set at installation time by changing the defaults in the Natural program AOSEX1. The table below lists the parameters and possible values. Default values are underlined:

Parameter	Valid Values / Default	Function
AOS-END-MSG	Yes (Y) / No (N)	Display the AOS demo version end-of-session message?
AOS-LOGO	Yes (Y) / No (N)	Display the AOS demo version logo?
CPEXLIST	No (N): normal list Yes (Y): extended	Display extended checkpoint list?
MAX-AC-IOS	0-999999 (150)	AC read converter block threshold value
NR-EXT	1, 2, 3, 4, 5	Critical extent threshold for listing file
STATINTV	1-9999 seconds (60)	Statistics gathering interval

To change the defaults, you must edit the Natural AOSEX1 program and make the changes directly within the program listing in the defaults area, as shown by the following example:

```

DEFINE DATA PARAMETER USING ADVPUX1
END-DEFINE
*
* SET THE DEFAULTS
*
AOS-END-MSG = 'Y' (Display end-of-session message)
AOS-LOGO = 'Y' (Online System logo display-set to 'N' for no logo display)
CPEXLIST = 'N' (Checkpoint list control: set to 'Y' for extended checkpoint list)
NR-EXT = 4 (Critical extent threshold: 1, 2, 3, 4 or 5)
MAX-AC-IOS = 150 (AC read converter block threshold)
STATINTV = 60 (Statistic gathering time interval: range: 1 - 9999)
*
END
    
```

# 7 Installing The Recovery Aid (ADARAI)

---

- ADARAI Installation Overview ..... 50
- ADARAI Installation Procedure ..... 50

This section describes how to install the Adabas Recovery Aid (ADARAI).

## ADARAI Installation Overview

---

To install the Adabas Recovery Aid, it is necessary to:

- allocate the recovery log;
- customize the skeleton job streams for your installation (see the *Adabas Operations* documentation for more detailed information);
- update the necessary nucleus run/utility job control to include the Recovery Aid data definition statements;
- install the Adabas/ADARAI utility configuration; and
- run ADARAI PREPARE and a save operation to begin a logging generation.

## ADARAI Installation Procedure

---

Except for customizing the skeleton job stream, the specific installation steps are as follows:

### ► To install the Adabas Recovery Aid:

#### 1 Define and format the recovery log files

The DDRLOGR1 and DDRLOGM1 files must be on the same device type.

Use the ADAFRM RLOGFRM function to format the RLOGs.

Use the ADAFRM RLOGFRM MIRROR parameter to format the DDRLOGM1 file.

#### 2 Add data definition statements for the recovery log files

Add DDRLOGR1 and DDRLOGM1 DD statements to the nucleus job stream and to any utilities that update or save the database and thus write to the RLOG files.

Whenever these utilities are executed while ADARAI is active in the database (that is, after the PREPARE function has been executed), the DDRLOGR1 and DDRLOGM1 DD statements must be included.

The following utilities update the database and therefore write to the RLOG:

```

ADAORD (all STORE and REORDER functions)
ADALOD (all functions)
ADAINV (all functions)
ADARES REGENERATE/BACKOUT database
ADASAV RESTORE (all functions) and RESTPLOG
ADADEF NEWWORK

```

The following utilities save the database and therefore write to the RLOG:

```

ADASAV SAVE (all functions)
ADAORD RESTRUCTURE
ADAULD

```

The following utility functions have an impact on recovery and therefore write to the RLOG:

```

ADARES PLCOPY/COPY
ADASAV MERGE

```

Additionally, the Adabas nucleus writes to the RLOG during startup and termination. The nucleus also writes checkpoint information to the RLOG when ADADBS or Adabas Online System functions are processed, ensuring these events are known to ADARAI for recovery processing.

- 3 Install ADARAI on the database.

Execute the ADARAI PREPARE function. ADARAI PREPARE updates the ASSO GCBs to indicate that ADARAI is installed. It also creates a control record on the RLOG file with necessary ADARAI information (number of generations, RLOG size, etc.).

- 4 Create the first ADARAI generation.

Execute ADASAV SAVE (database) to start the logging of RLOG information. See the *Adabas Utilities* documentation for more information.

Once ADARAI is active in the database, protection logging must always be used.

# 8

## Adabas Dump Formatting Tool (ADAFDP)

---

- ADAFDP Function ..... 54
- ADAFDP Output ..... 54

This section describes the use of the Adabas dump formatting tool ADAFDP.

## ADAFDP Function

---

ADAFDP is the address space dump formatting module. During abnormal shutdown of the Adabas nucleus, this module receives control to format and display information that should help you analyze the reason for the error.

During a nucleus shutdown, ADAMPM determines the shutdown reason. If the reason is abnormal termination, ADAMPM loads the ADAFDP module into the address space prior to the 20 call to the Adabas SVC. ADAFDP subsequently receives control to format nucleus information.

If ADAFDP cannot be loaded, message ADAF03 is written to the console and abnormal shutdown continues.

## ADAFDP Output

---

Much of the information formatted by ADAFDP is self-explanatory. However, because the type and amount of information depends on the shutdown situation, a summary of ADAFDP output is provided in this section.

- [ADAFDP Messages](#)
- [Pool Abbreviations](#)
- [User Threads](#)
- [Command Information](#)
- [RABN Information](#)

### ADAFDP Messages

Message	Description
ADAH51 / ADAH52	The message is displayed on the console and written to DDPRINT at the point where the format begins and terminates.
ADAMPM ABEND CODE and PSW	If an abend code and program status word (PSW) were saved in ADAMPM by the Adabas ESTAE, ADAFDP displays these. In addition, ADAFDP determines the module whose entry point best fits the PSW and calculates the offset within that module. If the ADAMPM abend code and PSW are zero, ADAFDP does not format this information.
ADABAS MODULE LOCATIONS	ADAFDP formats and displays the location of each of the Adabas nucleus modules resident in the address space.
ADDRESS LOCATIONS FOR USER EXITS	ADAFDP formats and displays the location of any user exit loaded with the Adabas nucleus.

Message	Description
ADDRESS LOCATIONS FOR HYPEREXITS	ADAFDP formats and displays the location of any hyperexit loaded with the Adabas nucleus. Hyperexits 10-31 are displayed as A-U, respectively.
ADANC0 STANDARD REGISTER SAVE AREA	Registers 0-7/8-F, which are saved in ADANC0. ADAFDP determines if any of these registers contains an address that points at a nucleus pool in storage. If yes, ADAFDP indicates which pool and snaps storage at that address. If the register is 12 and it points to a user thread, ADAFDP snaps the entire thread.
ADANC0 ABEND SAVE REGISTERS	Registers 0-7/8-F, which are saved in ADANC0 as a result of a user abend. ADAFDP determines if any of these saved registers contains an address that points at a nucleus pool in storage. If yes, ADAFDP indicates which pool and snaps storage at that location. If the saved register is 12 and it points to a user thread, ADAFDP snaps the entire thread.
ADAMPM SAVE REGISTERS	Registers 0-7/8-F, which were saved in ADAMPM by the Adabas ESTAE. These are the same registers displayed with the ADAM99 message. ADAFDP determines if any of these saved registers contains an address that points within a nucleus pool in storage. If yes, ADAFDP indicates which pool and snaps storage at that location.
BEGIN / ENDING ADDRESSES OF POOLS / TABLES	ADAFDP determines begin/ending address locations for pools and tables for the Adabas nucleus. These addresses are presented for easy location in the actual dump. See <a href="#">Pool Abbreviations</a> for more information.
ADABAS THREADS	ADAFDP formats the physical threads including threads 0, -1, and -2. The number of lines depends on the value of NT. The thread that was active at the time of the abnormal termination (if any) is marked by a pointer “->”.
USER THREADS	For any of the threads -2 to NT that had assigned work to perform, ADAFDP formats and displays information about the status of that thread. See <a href="#">User Threads</a> for more information:
FOLLOWING COMMANDS WERE FOUND IN THE CMD QUEUE	ADAFDP scans the command queue and formats information for any command found in the queue. See <a href="#">Command Information</a> for more information.
POOL INTEGRITY CHECK	ADAFDP check the integrity of several pools within the Adabas nucleus address space. If an error is detected within that pool, ADAFDP indicates which pool and what type of error was encountered. In addition, ADAFDP snaps storage at the location where the error was detected.
FOLLOWING RABNS / FILES ACTIVE IN BUFFER POOL	ADAFDP scans the buffer pool header for RABNs that were active or being updated. See <a href="#">RABN Information</a> for more information.
ADAIOR REGS FOUND AT OFFSET X'080'	Registers 0-7/8-F found saved in ADAIOR at this offset. If ADAFDP determines that any of these register values is pointing within an Adabas pool, it snaps storage at that location.
ADAIOR REGS FOUND AT OFFSET X'0C0'	Registers 0-7/8-F found saved in ADAIOR at this offset. If ADAFDP determines that any of these register values is pointing within an Adabas pool, it snaps storage at that location.
ICCB POINTED FROM X'A0' IN IOR	The ICCB address to which this offset in ADAIOR points.

Message	Description
ADAI22 ADAIOR TRACE TABLE	Format of ADAIOR trace table; same as that found with the ADAM99 message.

### Pool Abbreviations

Pool Abbreviation	Description
LOG	Log area
OPR	Adabas nucleus operator command processing area
CQ	Address of the command queue, which is formatted later by ADAFDP
ICQ	Internal command queue
TT	Thread table
IA1	Software AG internal area 1
SFT	Session file table
FU	File usage table
FUP	File update table
IOT	I/O table for asynchronous buffer flushing
PL2	PLOG area for asynchronous buffer flushing
PET	Table of posted ETs
TPT	Tpost
TPL	Tplatz
UQP	Unique descriptor pool
UHQ	Upper hold queue
HQ	Hold queue
UUQ	Upper user queue
UQ	User queue
FP	Format pool
FHF	File HILF element
PA	Protection area
TBI	Table of ISNs
TBQ	Table of sequential searches
WK3	Work part 3 space allocation table
IA2	Software AG internal area 2
WK2	Work part 2 space allocation table
VOL	VOLSER table
WIO	Work block I/O area
FST	Free space table work area

Pool Abbreviation	Description
UT	User threads
WP	Work pool
AW2	Work block asynchronous I/O area
IOP	I/O pool related to asynchronous buffer flush
IU2	Buffer pool importance header upper 2
IU1	Buffer pool importance header upper 1
BU2	Buffer pool upper header 2
BU1	Buffer pool upper header 1
BH	Address location of the buffer pool header, information from the buffer pool header is formatted later by ADAFDP
BP	Address location of the physical start of the buffer pool

## User Threads

Information	Description
Thread Number	-2 to NT
Status	Indicates the current status of the thread. The following statuses are possible: <ul style="list-style-type: none"> <li>■ *Active*: the currently active thread</li> <li>■ In Use: thread has been assigned work</li> <li>■ Waiting For I/O: waiting for a block not in buffer pool</li> <li>■ Waiting For RABN: waiting for a RABN already in use</li> <li>■ Waiting For Work-2 Area Block: similar to waiting for I/O</li> <li>■ Waiting Workpool Space: provides number of bytes in decimal</li> <li>■ Ready To Run: waiting to be selected for execution</li> </ul>
CMD	The Adabas command being executed
Response Code	Response code (if any)
File Number	File number for this command
ISN	Internal sequence number for this command
Sub. Rsp	Subroutine response code (if any)
Last RABN for I/O	Last RABN required by command processing, in decimal
Type	Last RABN type (A - ASSO, D - DATA)
CQE Addr	Command queue element address for this command
User Jobname	Job name for user who executed this command
ITID	Internal Adabas ID for user who executed this command
User	User ID for user who executed this command

Information	Description
Unique global ID	28-byte ID for user who owns this command
Buffer Addresses	buffer addresses for: control block, format buffer, search buffer, value buffer, ISN buffer
Buffer Lengths	FL: format buffer length RL: record buffer length SL: search buffer length VL: value buffer length IL: ISN buffer length
Snap Thread	The first 144 bytes of the user thread are snapped

### Command Information

Information	Description
CQE Address	The address location of this CQE
F	<p>Command queue flag bytes:</p> <ul style="list-style-type: none"> <li>■ First Byte: General Purpose Flag                             <ul style="list-style-type: none"> <li>■ X'80': User buffers in service partition, region, address space</li> <li>■ X'40': ET command waiting for 12 call</li> <li>■ X'20': Waiting for 16 call</li> <li>■ X'10': 16 call required</li> <li>■ X'08': Attached buffer</li> <li>■ X'04': Attached buffer required</li> <li>■ X'02': X-memory lock held (z/OS only)</li> </ul> </li> <li>■ Second Byte: Selection Flag                             <ul style="list-style-type: none"> <li>■ X'80': In process</li> <li>■ X'40': Ready to be selected</li> <li>■ X'20': Search for UQE done</li> <li>■ X'10': UQE found</li> <li>■ X'08': Not selectable during BSS=x'80' status</li> <li>■ X'04': Not selectable during ET-SYNC</li> <li>■ X'02': Waiting for space</li> <li>■ X'01': Waiting for ISN in HQ</li> </ul> </li> </ul>
CMD	The command type
File Number	The file number for this command
Job Name	Job name for the user
Addr User	UQE Address of users UQE, if searched for and found
Addr User ASCB	Address location of user's ASCB

Information	Description
Addr ECB	Address location of user's ECB (in user's address space)
Addr User UB	Address of users UB (in user's address space)
Addr User PAL	Address location of user's parameter address list
CQE ACA	ACA field of CQE.
CQE RQST	RQST field of CQE
Abuf/Pal	Address of the attached buffer/parameter address list (PAL) for CMD
Comm Id	28-byte unique user ID for this command

### RABN Information

Information	Description
RABN Number	The RABN number in decimal
Type	Type of block (A - ASSO, D - DATA)
Flag	BP header element flag byte: <ul style="list-style-type: none"> <li>■ AKZ X'40': Active indicator</li> <li>■ UKZ X'20': Update indicator</li> <li>■ RKZ X'10': Read indicator</li> <li>■ XKZ X'04': Access is waiting for block</li> <li>■ YKZ X'02': Update is waiting for block</li> <li>■ SKZ X'01': Write indicator</li> </ul>
File	File number that owns this block
Address	Address location of block in storage.

# 9 ADAUTM (Universal Transaction Monitor Support)

---

- Common Synchronization Points ..... 62
- The UTM Transaction Concept ..... 62
- Comments and Limitations ..... 63
- ADAUTM Functions ..... 63
- ADAUTM Installation ..... 69
- ADAUTM Diagnostic Information ..... 72

Software AG provides ADAUTM to coordinate Adabas database operations with the SNI BS2000 systems running the Universal Transaction Monitor (UTM).

This section describes ADAUTM function, installation and operation.

## Common Synchronization Points

---

To safely operate SNI's Universal Transaction Monitor (UTM) and a database, both systems must be able to run separately and coordinate their restarts. That is the only way to synchronize a database transaction running inside a UTM transaction.

ADAUTM makes it possible to have a common point of synchronization and thereby to set the whole transaction back to the last common synchronization point, if needed.

Both Adabas and UTM define points of synchronization ("sync points"):

- Adabas defines a sync point at the end of the database transaction;
- UTM defines a sync point at the end of a UTM transaction.

In some cases, these sync points are common to both Adabas and UTM. If an emergency restart should be necessary, both of the systems can set the interrupted transactions back to the last common sync point.

A database connection module (DBCON) is used for communication between UTM, its user program, and Adabas. The use of synchronization mode is controlled by a parameter in the UTM utility KDCDEF.

## The UTM Transaction Concept

---

The UTM transaction concept is to be referenced to the database access here only.

Each UTM user program starts a transaction using an INIT call and ends with a PEND *nn*. When *nn* takes on the value RE or FI, UTM writes a synchronization point followed by an end-of-transaction for the database transaction. Normally, a user program determines the end of a database transaction. In an Adabas environment, the DBCON can take over that task. After an end-of-transaction ET for a database, no more calls to this database are allowed within the current UTM transaction.

## Comments and Limitations

---

DBCON is invoked from UTM only if it occurs on a TP/DB transaction. If the last transaction within a UTM process is a pure TP transaction, the start parameter VG-ENDE=CL cannot be carried out at the end of the UTM process.

A 16-byte prefix of ET data is written at every sync point, in the order of synchronization. This prefix is transparent to the user. This means that when a UTM process contains more than one UTM transaction and the user wants the ET data to be available after the end of the process, the ET data must be written at every ET or with the last ET/CL for this DB transaction. Otherwise, the former ET data will be overwritten by the prefix.

A UTM process imposes only a few limitations on ADAUTM at this time. Those limitations refer only to the Adabas commands OP, ET, and BT. When using an OP command, the R option cannot be used if a process contains more than one UTM transaction because the record buffer is not available after the end of a database transaction. In case of ET and BT, the ISN hold option cannot be used.

The length of ET data that can be used is limited to 1984 bytes for users.

## ADAUTM Functions

---

In the database transaction process, all calls to the database are transferred to DBCON to be checked. The start, update, and end of transaction are the most important parts.

At the start, a transaction is checked to see if the first call is an OP command and if so, whether the Additions 1 field of the Adabas control block contains a valid value. If the Additions 1 field does not contain a valid string, a generic one is created and inserted. If the first command is not an OP command, such a command is carried out implicitly; after that, the user's order is handed over to Adabas.

All commands that have, either explicitly or implicitly, an attribute update are checked. The database ID of the first commands of that category of a transaction is marked as a update database for this transaction. That means that it is not allowed to carry out updates for more than one database within one database transaction.

Usually, the user initiates the end of transaction by issuing an ET/CL command. If that is not the case, the DBCON generates the UTM end of transaction. At this point, calls to the database are not permitted until the end of the UTM transaction (otherwise, the whole transaction must be set back to the last sync point).

When processing a UTM transaction, the main task is to handle the end of transaction procedure. Here, the synchronization with the database is done. In any case, ET data written for synchronization

purposes is transparent to the user. Another listed function is the backout of a TP/DB transaction, as well as the functions with special positions, such as those to process status information. That special function is used during emergency restart before UTM is active.

- Establishing and Terminating a Connection
- User Call
- UTM End of Transaction
- UTM Transaction Backout
- Coordinated Restart
- User Exit 1

## **Establishing and Terminating a Connection**

- Connecting to Adabas
- Disconnecting from Adabas

### **Connecting to Adabas**

The initial link may be subdivided into the following parts:

- setting default values that are not defined at session startup, using the appropriate parameters

All parameters that did not acquire a value during the start of the UTM session are now initialized by a default value. These defaults are described in a later section.

- creating the internal administration tables

A table is built that contains information about the user and the user's transactions. The table is installed as a common memory pool. The value of the parameter `APPLI-ID` is used as part of the pool's name.

- making the database and the running mode available

### **Disconnecting from Adabas**

When disconnecting from Adabas, the administration pool is closed in accordance with BS2000 conventions.

## User Call

All user calls to Adabas pass through this function. Here, all the necessary checks are carried out. These checks refer to the synchronization of the TP and DB transaction, but not to the syntax of the Adabas commands or their buffers. The functionality is described with an example of a UTM transaction that contains accesses to a database.

At the beginning, DBCON determines whether the current database call is the first within the UTM transaction. If it is the first call, DBCON determines whether it is an `OP` (open) command call to initiate an Adabas transaction. If it is not an `OP` command, an internal `OP` is performed after the user's call is completed.

DBCON also determines whether a command leads or could lead to an update in any form. If so, the database ID is recorded. With the occurrence of the first update-type command, DBCON marks the transaction as an update transaction. From that point, updates may only be done on this database during this transaction. Modifications to any other databases are rejected as errors, and the whole transaction is set back.

At the end of a database transaction, the `ET/CL` (end-of-transaction/close) commands are not passed immediately to Adabas, but instead are delayed until the end of the UTM transaction. This means that between the end of a database transaction and the end of the related UTM transaction, no more calls to the database can be carried out. Any attempt to execute such calls leads to a backout of that transaction. At the end of the UTM transaction, it is determined whether the user has determined the end of the transaction, or if DBCON must end it internally.

- User Open
- Internal Open

## User Open

If the field `ACBADD1` contains a value equal to zero or blank, DBCON tries to find an `ET` data ID in the administration pool (subsequent transaction within a UTM process). When available, this ID is taken over into `ACBADD1`; otherwise, an ID is built by the constant `ADAU`, the `APPLI-ID`, and an internal number. If a user exit is available, it gets control in order to modify the passed Adabas control block. The only change the exit can make is to modify the value in `ACBADD1`. After the DBCON gets back control, it overwrites the field with the old value if the exit has changed it to zero or blank, or the `ET` data ID was changed after the first transaction of this process.

## Internal Open

If the first database call is not an `OP` command and `ET-MODE=AUTO` (the default) is activated, `DBCON` determines whether or not this is a subsequent transaction within the current UTM process. If it is, the call will be executed. If Adabas returns the call with a response code 9, an internal `OP` command is created and executed; after that, the user's call is repeated. At the beginning of a UTM process, an internal `OP` command is created, carried out, and after that, the user call. The internally generated `OP` command is passed to the user exit in both cases. See also the section [User Exit 1](#).

## UTM End of Transaction

The function `PEND` with one of the attributes `RE`, `FI`, or `FC` determines the end of transaction of UTM. The `TP` transaction end also contains an end of a `DB` transaction. That means that now the commands `ET/CL` are carried out. These were delivered either by the user, or must be created by the `DBCON` now. `ET/CL` commands always get an "E" option in the Adabas control block. Before Adabas is called, the `DBCON` passes the command through to the exit. After a successful execution of the command with a `PEND-RE`, data about this transaction is stored in the administration pool.

## UTM Transaction Backout

This function is called by UTM if a user executes a `RESET` or `PEND-ER` call. The `DBCON` calls this for itself if the database is not available or an error occurs during the end of transaction procedure. Adabas return codes that occur during a transaction are passed directly back to the user and do not lead to a backout of the transaction.

## Coordinated Restart

The coordinated restart contains two functions which are called during the phase of emergency restart and/or the normal end of the application. An emergency restart indicates an abnormal end of the last UTM session. At a new start of the application, one of two conditions may occur:

- there are open transactions
- there are no open transactions

While the UTM transaction is still open, it must be determined whether or not the database transaction is also still open. This occurs as described below.

In the case of emergency restart, the `DBCON` is called by the order `Check DB Status` for update transaction. At first, the `ET` data belonging to the update database are read. Then all read-only database operations are handled in the same way. The following situations may occur:

- if the synchronization data of UTM are equal to that read from the update database `ET` data header, the transaction is marked as finished for UTM.

- if the synchronization data of UTM are not equal, the complete DB transaction is backed out (BT) and UTM is informed with “transaction cancelled”. If Adabas returns a response code unequal to 9 or 22, the process is stopped. The UTM utility KDCDEF may be required.

If there are no open transactions, UTM requires the DBCON to delete all information needed for synchronization. In addition, after a normal end of the last UTM session, the DBCON is required to delete all information.

## User Exit 1

User Exit 1 can be used to influence the Adabas commands `OP`, `ET`, and `CL`.

However, User Exit 1 can only modify the commands which are offered; it cannot execute its own Adabas command because control is not passed back after executing such a command.

The Adabas control block and the record buffer may be modified depending on the commands being used.

The field `E1PARB` contains the address of the `ET` data area provided by ADAUTM. The address at `E1PARB` points to a field which contains the record length and is a part of a 16-byte header. With the exception of the length field, the header cannot be modified. The current length of the new data, plus 16 (the length of the header) must be set in the length field.

- [Processing at the Start of a UTM Process](#)
- [Processing at the End of a UTM Update Transaction/Process](#)
- [User Exit Parameter List](#)

### Processing at the Start of a UTM Process

The read `ET` data option with the `OP` command cannot be inserted by the exit. The value that can be modified is the `ET` data ID in the Additions 1 field of the Adabas control block.

The `ET` data ID can only be modified at the beginning of a UTM process. It cannot be modified after a `PEND RE` if the DBCON has to issue an `OP` (after an Adabas error 9).

When using an `OP` command, only the fields `E1PFB` and `E1PARB` can be modified.

The `ET` data ID in the Additions 1 field can only be modified as follows:

- If bit `E1PAR` is on, the `ET` data ID cannot be modified.
- Bit `E1POP` and `E1PIO` allow the `ET` data ID to be modified; however, they cannot be changed to either zero or blank.

### Processing at the End of a UTM Update Transaction/Process

An update transaction at the end of a UTM transaction or process can exchange ET/CL commands with each other and/or make ET data available.

At the end of a UTM transaction/process, the following conventions apply:

- User Exit 1 gets control only for an update transaction
- the contents of the Adabas command field may only be modified by the exit according to the start parameter VG-ENDE
- checks must not occur after returning from the exit
- the ET data ID may not be modified because its range of validity is the UTM process. ET data itself may be changed; the exit must provide the new data in its own area.
- the current length must be delivered in the field Length of the record buffer in the Adabas control block

If the exit sets the bit E1PFBRE, ADAUTM moves the data into its own area; otherwise, no user ET data are written.

A maximum of 1984 bytes of user ET data are allowed.

If there was an internal ET/CL, the field E1PARB contains low-value.

### User Exit Parameter List

The following description contains the action fields of the parameter list. The complete list can be taken from the Assembler DSECT EX1PARAM.

```
E1PTAS1
E1POP: User with its own OPEN command.
E1PAR: If the first command is not an OPEN after PEND RE, it is done after response ←
code 9.
E1PIO: It is provided an internal OPEN command.
E1PFB
E1PFBCO : EXIT1 has modified the ACB during an OPEN
E1PFBCE : EXIT1 has modified the ACB during an ET/CL command.
E1PFBRE : EXIT1 has modified the RB during an ET/CL command.
E1PACB Address of ACB, either of the user or of ADAUTM.
E1PARB Address of RB; will be delivered by ADAUTM or is equal to zero using an ←
internal ET/CL.
The exit 1 provides an address of its own record buffer, if an internal ET/CL occurs.
```

The exit is called by the standard BALR interface of the Assembler language. The following registers are used:

```

R01 : Address of the parameter list
R13 : Address of the save area
R14 : Return address
R15 : Start address of the modules

```

## ADAUTM Installation

To make a coordinated restart possible, the DBCON (ADAUTM) must be specified in the UTM root module of the application. This is done by using the DATABASE statement in the UTM utility KDCDEF. The DATABASE statement defines the database in the source of the UTM root. In addition, the ADAUTM modules and the Adabas link module must be provided for the linkage editor's run.

- [Installation Procedure](#)
- [ADAUTM Parameters](#)
- [ADAUTM Parameter Example](#)

### Installation Procedure

The following procedure must be used to install ADAUTM.

#### ▶ To install ADAUTM:

- 1 Run KDCDEF with:

```
DATABASE TYPE=DB,ENTRY=xyz
```

— where ENTRY=xyz must match the name used in Adabas calls (usually “ADABAS”). If ENTRY is omitted or specified as “DB”, ENTRY=ADABAS is generated.

The LIB parameter of the DATABASE statement does not apply for ADAUTM because ADAUTM must be statically linked with KDCROOT.

- 2 Assemble KDCROOT with the macro library AUT $nnn$ .MAC where  $nnn$  is the ADAUTM version, revision, and SM level numbers).
- 3 Link the UTM application with:
  - AUTDB $mm$  from AUT $nnn$ .MOD where  $mm$  is the TM version (31, 32, 33, 34, and 40 are supported);
  - AUTNUC from AUT $nnn$ .MOD; and
  - ADAUSER from ADA $nnn$ .MOD

Usually, KDCROOT will contain an entry point ADABAS for Adabas calls. ADAUSER also has a symbol ADABAS. It is therefore necessary to rename this symbol on binding ADAUSER. In \$TSOLINK, specify:

```
RENAME ADABAS,ADABASX
INCLUDE ADAUSER,SAG.ADALIB
```

Alternatively, if using the Binder, specify:

```
INCLUDE-MODULES LIB=&ADA,ELE=ADAUSER,TYP=R
RENAME-SYMBOL SYMBOL-NAME=ADABAS,NEW-NAME=ADABASX
```

- 4 Add ADAUTM parameters to the UTM startup parameters in the UTM startup procedure.

### ADAUTM Parameters

This section describes the ADAUTM parameters.

#### ADAUTM Parameter Syntax

The syntax of an ADAUTM parameter is

```
.DB ADABAS parameter = value
```

If the prefix “.DB ADABAS” is omitted, UTM sends the message "K38 -Parameter Error-". The application ends abnormally.

#### ADAUTM Parameters

Parameter	Description	Possible Values	Default
DATABASE DA DB	Default database ID that is the update database for the current session.	1 - 65536	1
APPLI-ID AID	Required. The short name of the UTM application. The application ID identifies the UTM application running against Adabas. This value becomes part of the name of the common memory pool. That means that, in accordance with the parameter SCOPE, a default value may lead to an error of the UTM process administration.	1 - 9999	1
ET-MODE ETM	ADAUTM generates the OP, ET, CL commands if the application does not do it.  ETM=AUTO will cause an OP command to be generated at the beginning of a database transaction, and an ET/CL command is automatically executed at the end of a UTM or database	AUTO   MAN	AUTO

Parameter	Description	Possible Values	Default
	transaction, when necessary. Both are required for synchronization.  ETM=MAN disables this function.		
VG-ENDE VGE	Generate a CL instead of an ET command at the end of the UTM process.  VGE=CL generates a CL command for the Adabas transaction if the UTM transaction finishes with PEND FI/FC; otherwise, an ET is generated.	CL   ET	ET
UEX1	The name of the user exit that gets control during OP/ET/CL commands.  Name of the module that is linked from a library with the link name DDLIB.	module name	(none)
SCOPE	Accessibility of the common memory pool for ADAUTM.  SCOPE applies only for TASKTYPE "BATCHTASK" and "TP". If TASKTYPE is "INTERACTIV", the scope of the common memory pool is always "TASK".	USERID   SYSTEM   TASK   USER_GROUP	USERID
UID-ADA	How the last 8 bytes of the Adabas communication ID are built by ADAUTM.  UID-ADA=KCBENID: the KB field KCBENID is used  UID-ADA=KCLOGTER: the KB field KCLOGTER is used  UID-ADA=VGNR: the rightmost 4-bytes are built using the UTM conversation ID, as in releases of Adabas prior to 6.1, and the leftmost 4 bytes (the prefix) are specified by the UID-PRF parameter.	KCBENID   KCLOGTER   VGNR	VGNR
UID-PRF	If the UID-ADA parameter value is "VGNR", this parameter specifies the leftmost 4 bytes.	abcd	(none)

### ADAUTM Parameter Example

The following is an example of ADAUTM parameter usage:

```
.DB ADABAS DB = 002 , AID = 80
.DB ADABAS VG-ENDE = CL , SCOPE = USERID
.DB ADABAS ET-MODE = AUTO
.DB ADABAS UEX1 = ADAEX1
```

## ADAUTM Diagnostic Information

---

ADAUTM diagnostic information is written to UTM's DB-DIAGAREA and to SYSOUT.

- [UTM DB-DIAGAREA](#)
- [Messages to SYSOUT](#)
- [ADAUTM Message Codes](#)

### UTM DB-DIAGAREA

The general layout and use of the DB-DIAG-AREA area are described in the appropriate UTM manual. The DB-DIAGAREA is written as follows:

- *primary*: DB trace information provides essential information in an ADAUTM response code
- *secondary*: DB trace information includes more detail; see the DSECT DDBTRAC generated by the macro DDBTRAC for the layout of the information

### Messages to SYSOUT

ADAUTM writes messages to SYSOUT in the format:

```
AUTxxxx date time OP=yyyy UID=abcdefgh DBID=nnnnn RSP=mmm
```

where

```
xxxx is the ADAUTM message code  
yyyy is the UTM primary opcode; see the UTM macro DBCONPAA  
abcdefgh is the last 8 bytes of the Adabas communication ID  
nnnnn is the Adabas database ID  
mmm is the Adabas nucleus response code
```

### ADAUTM Message Codes

This section describes the ADAUTM messages.

- [ADAUTM Message Format](#)
- [ADAUTM Messages](#)

▪ Handling Adabas Nucleus Response Codes

**ADAUTM Message Format**

ADAUTM message codes are 4 characters long in the following format:

*xnnn*

where

<i>x</i>	<p>is the type identifier. Possible values are:</p> <ul style="list-style-type: none"> <li>■ D (database): ADAUTM received a response code <i>nnn</i> from Adabas. With the exception of D148, Adabas response codes starting with D are not reported.</li> <li>■ I (internal): an error occurred in ADAUTM's handling of ET data</li> <li>■ P (parameter): an error occurred in ADAUTM's startup parameters</li> <li>■ S (system): ADAUTM received an error from a BS2000 executive macro; or, the installation is not correct</li> <li>■ U (user): ADAUTM received unsupported Adabas calls</li> </ul>
<i>nnn</i>	is the Adabas response code received by ADAUTM; see value D above.

**ADAUTM Messages**

The following table contains the ADAUTM response codes and messages:

Response Code	Message / Description
I100	Internal area for ET data exhausted
P100	Statement format invalid
P101	Unknown parameter
P102	Invalid continuation
P103	Prefix “.DB ADABAS” not correct
P104	Invalid length of statement
P105	Invalid value
P120	Value not numeric
P121	Numeric value out of range
S100	ENAMP error AUTPOOL
S101	REQMP error AUTPOOL
S102	DISMP error AUTPOOL
S106	ESQUTM not linked AUTCONC
S107	TRACE open error AUTCONC

Response Code	Message / Description
S108	ENQAR error AUTPOOL
S109	DEQAR error AUTPOOL
S110	ADALNQ not linked AUTMAIN
S111	Unsupported BS2000 version AUTMAIN
S112	Unsupported HSI version AUTMAIN
S113	HSITYPE error AUTMAIN
S114	TABLE error AUTMAIN
U100	More than four (4) DBIDs used in a single transaction.
U101	Update command issued between ET and end of UTM transaction.
U102	OP command issued, but ET or CL required.
U103	More than one update DBID used in a single transaction.

### Handling Adabas Nucleus Response Codes

When ADAUTM receives response code 148 from the Adabas nucleus, a “DBMS down” condition is reported to UTM.

# Index

---

## A

- Adabas
  - installation under BS2000/OSD, 1
- Adabas API, 24
- Adabas Dump Formatting Tool (ADAFDP), 53
- Adabas library disk space requirements, 9
- Adabas Recovery Aid (ADARAI)
  - installation, 49
- ADAFDP (see Adabas Dump Formatting tool (ADAFDP))
- ADARAI (see Adabas Recovery Aid (ADARAI))
- ADAUSER program, 25
- ADAUTM (see Universal Transaction Monitor support (ADAUTM))
- AOS demo version, 45

## B

- batch/TIAM TP monitor, 32
- BS2000 communication environment, 14
- BS2000 installation procedure, 5
- BS2000 logon ID, 9

## D

- DAB-supported volume restrictions, 10
- data conversion, 20
- database migration, 11
- device and file considerations, 37
- device block size general rules, 40
- device type considerations, 13

## E

- enabling Universal Encoding Support (UES) for your Adabas nucleus, 17
- error messages, 22
- ESD symbols, 25

## F

- formatting new data sets, 21

## I

- installation
  - applying zaps, 14
  - checklist, 6

- device type considerations, 13
- enabling UES support, 17
- formatting new data sets, 21
- installing the release tape, 11
- job switches, 16
- job variable handling, 15
- license file, 13
- linking LNKUES, 20
- linking user exits, 16
- preparation, 8
- TP monitors, 23
- under BS2000/OSD, 1
- using SMA, 11
- without SMA, 11
- installation procedure, 5
- internal product disk space requirements, 10
- interpreting BS2000 error messages, 22

## J

- job switches, 16
- job variable handling, 15

## L

- license file, 13
- linking LNKUES, 20
- linking user exits, 16

## M

- migrating databases, 11

## N

- nucleus address space requirements, 10

## P

- preparing to install Adabas, 8

## R

- release tape installation, 11
- requirements
  - Adabas database disk space requirements, 10
  - BS2000 logon ID, 9
  - data sets for UES, 9
  - disk space for Adabas library, 9

- internal product data set disk space, 10
- nucleus address space, 10
- restrictions
  - DAB-supported volumes, 10

## S

- SMA (see System Maintenance Aid (SMA))
- starting Adabas, 22
- supported BS2000 environments, 3
- System Maintenance Aid (SMA), 11

## T

- TDCE, 38
- teleprocessing monitor (TP) installation, 23
- translation tables, 75

## U

- UES (see universal encoding support (UES))
- UES database connection, 17
- UES support data sets, 9
- universal encoding support (UES), 9
- Universal Transaction Monitor support (ADAUTM), 61
- UTM installation, 33

## Z

- zaps, 14
