About this Guide

This book explains what the KnowledgeBase is and describes techniques used to modify the KnowledgeBase. Specific strategies and concepts are presented here so that you can customize your KnowledgeBase and still preserve its modular design. This book also describes structural aspects of host screens and the GUI results they engender.

Understanding how the KnowledgeBase functions is important for only a few members of the conversion team. This is because of the global effect the KnowledgeBase can have on an entire application. Only those with knowledge about the legacy application and the targeted GUI design need to understand how the KnowledgeBase functions. Preferably these are people in managerial positions.

The KnowledgeBase information presented here is strictly conceptual in nature. Reading this book does not make you a KnowledgeBase expert but, it does give you enough information to become one with practice.

This book deals with the following topics:

- **Chapter 1 - "Explanation of Symbols"** explains the symbols used in the tree diagrams in this book.
- **Chapter 2 - "KnowledgeBase Overview"** shows you how ACE reads host screens by breaking them down into units. The KnowledgeBase uses these pieces of information to create a GUI according to pre-established rules. These rules called **Pattern Definitions** are at the heart of the KnowledgeBase and can be customized.
- **Chapter 3 - "KnowledgeBase Concepts"** explains how the KnowledgeBase interprets those units of screen information. Concepts such as information sequences, patterns and hierarchy are factors which impact the KnowledgeBase. Understanding these concepts and how to recognize them is important when strict parameters controlling the GUI design are in effect.
- **Chapter 4 - "Modification Strategies"** gets you working inside the KnowledgeBase. Here you see many screen captures that guide you through all the examples. While reading this chapter you should have ACE launched with an application open so that you can work along with the examples in the book. Emphasis in this chapter is placed on the concepts of Choice Elements and Choice Sets.
- **Chapter 5 - "Selected Pattern Definitions"** unveils how Pattern Definitions are built, what character sequences they recognize and if modifications are allowed.

The following conventions are used throughout this manual.

Table 2. Documentation conventions

Convention	Description
Click	Position the mouse pointer on the control and quickly press and release the left mouse button once . (Unless the right mouse button is explicitly specified, you should click the left mouse button.)
Double-click	Position the mouse pointer on the control and quickly press and release the left mouse button twice . (Unless the right mouse button is explicitly specified, you should double-click the left mouse button.)
UPPERCASE	Uppercase letters are used for the names of files. For example, a panel file with the name Menu, will be expressed as MENU.PNL.
<i>italics</i>	Names of applications, programs, menus, dialog boxes, and libraries.
Bold	Menu options, and items, dialog boxes and items to be selected from a dialog box. The names of pull-down menus.
<i>Bold Italics</i>	Pattern definitions, representation definitions, message definitions, method names, layout names, section names, selection definitions, function definitions.
BOLD + UPPERCASE	Keyboard shortcuts: Press the SHIFT key. Press CTRL + Z .

Chapter 1. Explanation of Symbols

This book uses tree diagrams to illustrate the structure of Pattern Definitions:

Figure 1. Three diagrams that illustrate the structure of Pattern Definitions

In more detail:

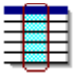

- The pattern *TimeOutputField* contains the child patterns *OutputAttr* and *OutputArea*.
- The  symbol indicates that *OutputArea* contains child patterns, but that these child patterns are not displayed on the diagram.
- The  symbol indicates that all the child patterns of *TimeOutputField* are displayed on the diagram.
- The two  symbols indicate that *TimeOutputField* and *OutputArea* are Horizontal Group type patterns.
- The  symbol indicates that *OutputAttr* is a Character Set type pattern.

Table of Symbols

The following table presents the meanings of each of the symbols used in the tree diagrams.

Chapter 2. KnowledgeBase Overview

The KnowledgeBase is a customizable tool in ACE which, when configured properly, recognizes all screens patterns in an application and automatically associates GUI representations to them. The key to making the most of the KnowledgeBase is modifying it to read your applications screens.

This chapter describes:

- What the KnowledgeBase does.
- How and when to modify the KnowledgeBase.
- How the KnowledgeBase reads screen information.
- Primary Patterns - the rules that control the KnowledgeBase.

ACE ships with many KnowledgeBase rules installed but, because legacy applications vary so widely there is a good chance your KnowledgeBase will need modifications to meet your applications particular needs. How and when you modify the KnowledgeBase depends on whether you want the effect to be local or global.

ACE works by breaking down the legacy screens into pieces of information. These pieces can be any combination of characters which the KnowledgeBase then reads. The rules that govern the KnowledgeBase in associating pieces of host information with GUI controls are called Pattern Definitions. Pattern Definitions are introduced here but, more detailed information on this topic is to come in subsequent chapters.

What the KnowledgeBase Does

ACE is a multifunction tool that enhances your legacy application by adding a graphical interface consistent with current operating systems. Additionally ACE allows you to include added functionality without re-coding the legacy application. Added functionality allows your legacy application to integrate present technologies, such as the World Wide Web, intranets, Java, Visual Basic, as well as future technologies. ACE uses the KnowledgeBase when it:

- Compares groups of host screen characters to KnowledgeBase Pattern Definitions and identifies which patterns are satisfied;
- Reads from the KnowledgeBase the Representation Components of an identified pattern and adds these components, both controls and methods, to the graphical interface. ACE

In order to accomplish this ACE must first perform the steps of converting a legacy host screen:

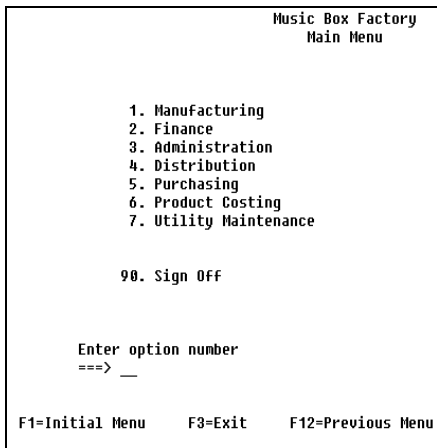

Figure 2. A legacy host screen

to a graphical interface:

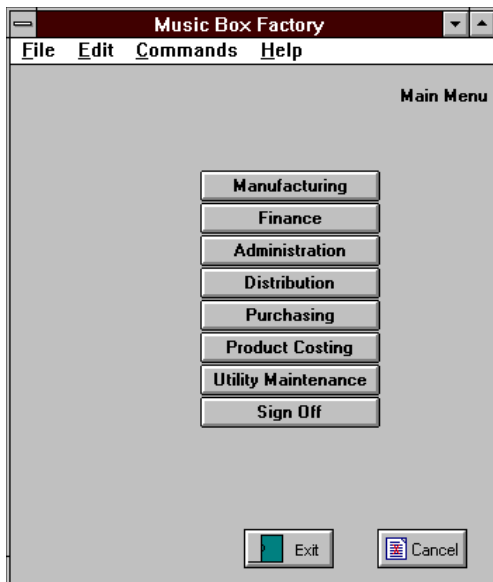

Figure 3. A graphical interface

This is accomplished by the KnowledgeBase.

The KnowledgeBase contains the rules ACE follows when it converts host screens to graphical user interfaces. These rules determine which controls appear on the GUI, as well as their size, color and position.

ACE uses the KnowledgeBase rules to:

- 1 Divide a host screen into several sections:

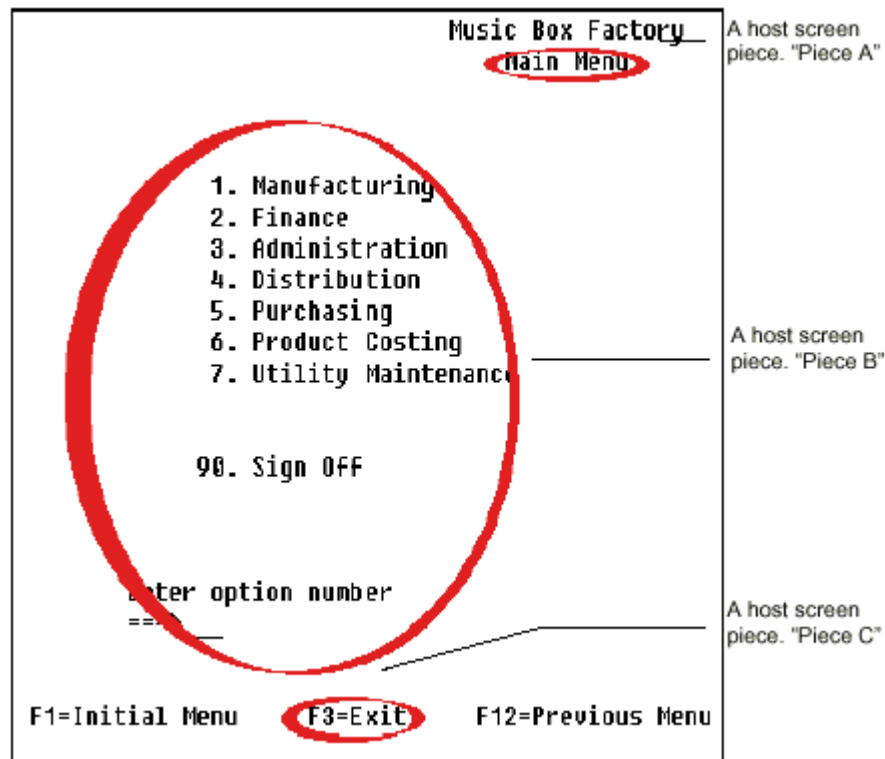

Figure 4. Dividing the host screen into sections

In this picture of a host screen, three of the host screen's pieces are circled.

- 2 Associate a graphic control with each host screen section, and determine the specifics, such as size and color, of each control:

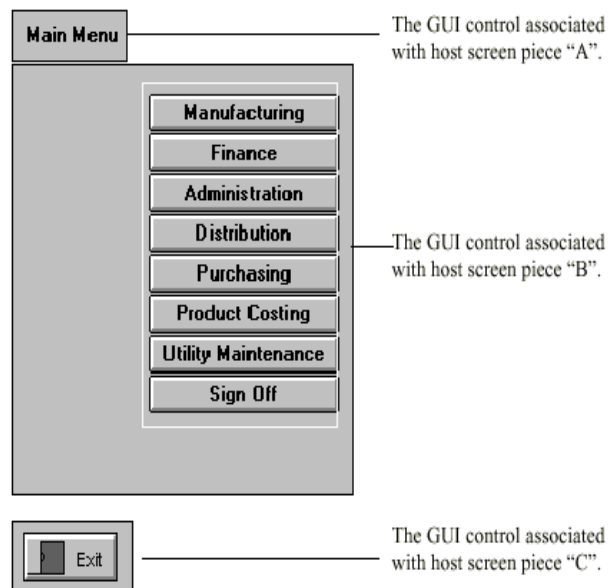

Figure 5. Associating graphical controls

3 Place each control on the graphical interface.

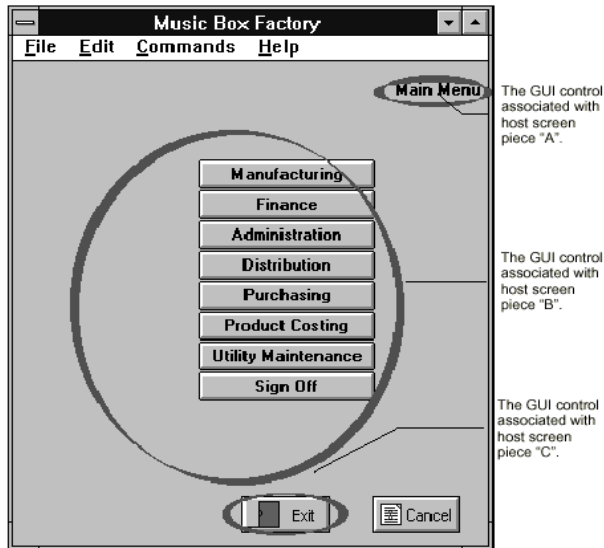

Figure 6. Placing controls onto the graphical interface

Modifying the KnowledgeBase

The ACE KnowledgeBase contains the rules ACE follows when it converts host screens to graphical interfaces. The ACE KnowledgeBase already contains a comprehensive set of rules when it ships. These rules reflect the standard interfaces of both host and graphical systems, and these rules allow ACE to provide basic functionality “out of the box.” Nevertheless, you will need to modify the KnowledgeBase to reflect the specific characteristics of your host application and to customize your application’s graphical interface.

When to Modify the KnowledgeBase

You must “instruct” ACE on how to handle the specific characteristics of your application, but your instructions will not always be via the KnowledgeBase. In general, it is faster to make a single change locally than it is to modify the KnowledgeBase.

Therefore, when you need to make a change because of a situation present on a single screen, you will probably make the change locally using Design View. However, when the item you are changing is present in several host screens, it is more efficient to make the change via the KnowledgeBase.

Advantages of Local Modifications

Local modifications are usually faster than KnowledgeBase modifications.

Modifying a Pattern Definition in the KnowledgeBase involves a few steps. Local modifications often require no more than placing a section boundary over an area of the screen.

Local modifications are easier to fine tune.

It is easier to change the position of a control, for instance, by dragging it than it is to modify the window layout. Visual composition is also easier with the window displayed.

Some situations can only be handled via local modifications.

There are some screen situations that can only be properly analyzed by a person who is familiar with the host application.

Advantages of KnowledgeBase Modifications

A modification that must be applied repeatedly is faster via the KnowledgeBase.

It takes less time to modify the KnowledgeBase than to modify many screens.

KnowledgeBase modifications help prevent mistakes and oversights.

It can be very tedious to apply the same local modification to screen after screen. When you are making a modification that involves several steps, you only have to “get it right” once when you perform the modification via the KnowledgeBase.

KnowledgeBase modifications ensure a standard look to the converted application.

A KnowledgeBase modification will affect the analysis and presentation of more than just the specific screen situation that needed better treatment. The KnowledgeBase modification will also affect the analysis and presentation of similar screen situations. Thus a single KnowledgeBase modification ensures that similar screen situations have similar GUI representations.

KnowledgeBase modifications ease maintenance.

A KnowledgeBase modification becomes an automatic part of the conversion process.

A new person who starts to work on an ongoing conversion does not have to be instructed in all the local modifications.

If new screens are added to the application, KnowledgeBase modifications will automatically be applied to them.

If you decide to alter the modification you only need to do it once. You do not have to apply the alteration individually to each affected screen. Moreover, you do not have to examine each screen to see if the alteration applies to that screen.

Pieces of Information

The KnowledgeBase rules divide the screen into pieces. These pieces are single pieces of complete, independent information. The division created by the KnowledgeBase rules is designed to be “natural.” The division is intended to reflect that different pieces of a host screen convey different pieces of information to you too.

Information Modularity

Pieces of host screen information have a modular structure. A result of the modular structure is that host screen pieces that contain different information can be similar in certain aspects.

The characters:

`F3=Exit`

form a piece of host screen information. The information is that pressing the **F3** key moves the application to the previous logical screen.

A different piece of information is conveyed by the characters

`F1=Initial Menu.`

The information here is that pressing the **F1** key moves the application to its Initial Menu screen.

These different pieces of information are similar because they have the same modular structure; they are formed from characters representing the key name, a separator character and characters describing the function of the named key:

Key Name Characters	F3, F1
Separator Character	=
Description Characters	Exit, Initial Menu

Thus, despite the fact that these two sequences contain different information, they are similar because their structure is the same.

Making Use of the Modularity

The modular structure of host screen information is very useful. It means that a piece of information can be identified via its structure no matter what the information is.

When you see characters representing a key-name, followed by a separator character, followed by additional words, you know that pressing the named key will have the effect described by the words. You may not understand the words, because you are not familiar with the application, or because the words are in a language you do not understand. However, the “structure” of the character sequence tells you that the sequence contains information about the effect of pressing a function key.

Information and the KnowledgeBase: Primary Patterns

The rules that the KnowledgeBase uses to associate complete pieces of host information with GUI controls are called Primary Patterns.

The Primary Patterns are independent of each other. A Primary Pattern associates a particular piece of host information with a particular GUI control without affecting which Primary Pattern associates any other piece of host information with a GUI control.

Modularity and the KnowledgeBase: Patterns

The KnowledgeBase Primary Patterns are built out of smaller patterns in a modular way. The modular construction of Primary Patterns out of smaller patterns is designed to reflect the modular structure of host information.

The ACE KnowledgeBase is designed to be modified in a way that preserves the modular construction of the Primary Patterns. Modifying the KnowledgeBase in this way:

- Preserves the independence of the Primary Patterns;
- Preserves the modular structure of the Primary Patterns.

The goal of this book is to teach you how to modify the KnowledgeBase in this “modular preserving” way. We strongly recommend that you modify the KnowledgeBase in this way such that the KnowledgeBase continues to reflect the modular structure of host information.

Chapter 3. KnowledgeBase Concepts

This introduction describes information concepts and how they are applied to host screens. The term information concepts is used here to describe host screen characters and character sequencing. Furthermore, character and character sequencing will pre-determine the structure of your Pattern Definitions.

This chapter describes:

- Information concepts.
- Information sequences.
- Pattern Definitions.

The KnowledgeBase uses the host screen information to create the GUI. In the first pages of this chapter you learn how information on the host screen is read by the KnowledgeBase. Complete information sequences convey a single piece of information about the host system or about a host operation. Partial information sequences, when combined, make up complete information sequences but do not by themselves convey information.

Pattern Definition is a term that you will read throughout ACE. The KnowledgeBase contains patterns, which are rules for classifying host screen characters and character groups. You can create new Pattern Definitions in order to classify any host screen character.

The concepts in this chapter are presented to you in two ways. The first explanation describes these information concepts using examples from everyday English. The second explanation describes the information concepts using typical host screen character sequences.

Information Concepts

Host applications present screen character information in many different ways. The KnowledgeBase uses the way this information is presented when creating the GUI. Information can be independent and stand alone, meaning it is not affected by other information. Whether or not the information is complete or partial also affects the workings of the KnowledgeBase.

Independence of Information

The sentence: *“The pitcher threw the ball past the batter for a strike.”* describes an event at a baseball game. When you read this sentence you understand the event *itself* in its entirety. The sentence conveys information to you.

The information in the example sentence above is independent of any other sentences that precede or follow it. Other sentences *add* information but they do not affect the information in the sentence itself.

Here are two examples which both use the above example sentence. In each example, a second sentence works together with the above sentence to add information, but the information in the first sentence is unchanged.

Example 1. Independence of information

“The pitcher threw the ball past the batter for a strike. The crowd roared in approval.”

The two sentences together tell you that the crowd favors the *pitching* team, but the information about the **event** is unchanged.

“The pitcher threw the ball past the batter for a strike. The crowd groaned in dismay.”

The two sentences together tell you that the crowd favors the *batting* team, but the information about the **event** is unchanged.

In both examples, the first sentence *“The pitcher ...”* conveys the **same** information to you about an event at a baseball game. In both examples the information is independent of the second sentence.

Completeness of Information

The information contained in the sentence *“The pitcher threw the ball past the batter for a strike.”* is complete. There is no ambiguity about the event described in the sentence.

The words that make up this sentence **do not** contain complete information, although they appear to. In the above sentence the word *“pitcher”* contributes information about a player in a baseball game. In the following sentence the word *“pitcher”* contributes information about a container for liquids:

“A pitcher of ice-cold lemonade.”

The word *“pitcher”* is ambiguous when standing by itself. You have no way of knowing whether *“pitcher”* means a baseball player or a container for liquids. The single word *“pitcher”* *does not convey complete information.*

Complete Information and Partial Information

The word “*pitcher*” can contribute information when it is part of a sentence, even though by itself it is ambiguous. The word “*pitcher*” can be described as partial information.

The concepts of independent information, complete information and partial information are also applicable to host screen characters.

Information Independence

The following piece of a host screen conveys an independent piece of information:

Figure 7. An independent piece of information

The characters and their position tell you that the current screen is a central takeoff point to other parts of the application. The information is independent of the menu items contained in the rest of the screen.

Information Completeness

The information is also complete. The characters “Main Menu” located at the top of the screen are sufficient to convey the purpose of the current screen.

Partial Information

The characters “Main Menu” by themselves are ambiguous. They do not necessarily convey information about the current location of the host application as they do in the example above. They might also contribute information about the function of a command key, as in the following character sequence:

`"F5=Main Menu"`

In this second example the characters “Main Menu” are a **part** of a complete piece of information. Together with the characters “F5” they convey that pressing the “F5” command key moves the application to the “Main Menu” screen.

In the first example, the characters “Main Menu” are a **part** of a complete piece of information. Together with their position at the top of a screen these characters convey that the current screen is the “main menu.”

Information and the KnowledgeBase

The KnowledgeBase works by formalizing the concept of information. The KnowledgeBase contains rules that specify when a sequence of host screen characters form a complete and independent piece of information. The KnowledgeBase rules also specify which graphical element is associated with a complete piece of information.

The KnowledgeBase needs to be modified when it fails to identify a complete piece of information, or when it fails to associate a complete piece of information with the correct graphical element.

The remainder of this chapter gives full details of complete information and partial information, and then continues with how these information concepts are reflected in the KnowledgeBase rules. The following chapter, which explains modification strategies, tells you how to maintain the information structure of the KnowledgeBase when you modify the KnowledgeBase rules.

Information Sequences

This section deals with the different types of Information Sequences.

Complete Information Sequences

A **Complete Information Sequence** is a group of host screen characters that conveys to you a single piece of information about the host system or about a host operation you can perform.

In Figure 8, the host screen characters form six groups. Each group is a Complete Information Sequence:

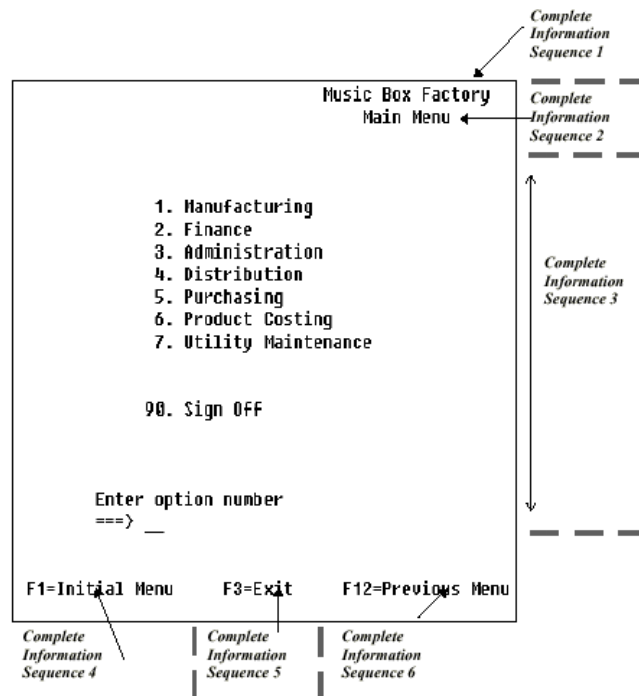

Figure 8. Complete information sequences

Complete Information Sequence 1

Music Box Factory

The character group is a Complete Information Sequence that identifies the host application.

Complete Information Sequence 2

Main Menu

The character group is a Complete Information Sequence that identifies the current screen within the host application.

Complete Information Sequence 3

- 1 Manufacturing
- 2 Finance
- 3 Administration
- 4 Distribution
- 5 Purchasing
- 6 Product Costing
- 7 Utility Maintenance

the information conveyed by “F3=Exit” is independent of the other characters on the screen.

Controls of the Graphical Interface correspond to Complete Information Sequences:

“F3=Exit” corresponds to: 

Different Complete Information Sequences can be:

- Informationally Identical, such as “F3=Exit” and “PF3 - Quit”
These two Information Sequences convey identical information. Each informs you that pressing the third function key causes the host application to move to the previous logical screen.

Informationally identical Information Sequences have identical Controls:

Sequence **Corresponds to:**

F3=Exit 

PF3 - Quit 

- Informationally Analogous, such as “F3=Exit” and “F12=Previous Menu”

These two Information Sequences convey analogous information. Each informs you that pressing the specified function key causes the host application to perform the specified operation.

Informationally analogous Information Sequences have similar Controls:

Sequence **Corresponds to:**

F3=Exit 

F12=Previous Menu 

- Informationally Unrelated, such as “F3=Exit” and “Music Box Factory”

These two Information Sequences convey different information. The first Sequence informs you that pressing the third function key causes the host

application to leave the current screen. The second Sequence tells you the name of the host application.

Informationally unrelated Information Sequences have unrelated Controls:

Sequence	Corresponds to:
F3=Exit	
Music Box Factory	

Partial Information Sequences

Partial Information Sequences are the building blocks of Complete Information Sequences. A group of characters is a Complete Information Sequence when:

- It contains Partial Information Sequences whose individual meanings combine to form a unit of information.
- The Partial Information Sequences appear in a logical order

The character group “F3=Exit” is a Complete Information Sequence composed of four Partial Information Sequences. Each Partial Information Sequence has its individual meaning:

Table 3. Partial information sequence descriptions

Partial Information Sequence:	Description:
F	Identifies any function key.
3	Identifies the specific member of a given set.
=	Bridges identification and descriptive characters.
Exit	Describes the Complete Information Sequence.

The character group “F3=Exit” is recognizable as a Complete Information Sequence because:

- It is made up of Partial Information Sequences that combine to form a unit of information;
- The Partial Information Sequences appear in a logical order.

Complete and Partial Information Sequences

The Partial Information Sequences that make up Complete Information Sequence have recognizable meanings but do not, by themselves, convey information:

The characters “Menu”

do **not** form a Complete Information Sequence; “Menu” by itself conveys no information. However, the character group “Menu” does have the meaning of a list of available options and it is therefore a Partial Information Sequence.

Note: It is important that “Menu” is not a Complete Information Sequence because we want a Complete Information Sequence to have a fixed GUI representation.

Example 2. Complete information sequences - character group ‘Menu’

In Figure 8, the character group “Menu” occurs three times:

“Main Menu”

“F1=Initial Menu”

“F12=Previous Menu”

The character group “Menu” cannot have a fixed representation.

Conventional Structure Within the KnowledgeBase

Complete Information Sequences have a conventional structure. The conventional structure is the type and order of the Partial Information Sequences that, *by convention*, make up the Complete Information Sequence.

It is necessary to use a “conventional structure” because a KnowledgeBase can only be finite and the number of possible Complete Information Sequences *that convey exactly the same information* is infinite. The conventional structure within the ACE KnowledgeBase reflects the most common forms of host Complete Information Sequences.

Examples of conventional and unconventional structure are given immediately below.

Complete Information Sequences with Conventional Structure

Example 3 illustrates complete information sequences with a conventional structure.

Example 3. Complete information sequences with a conventional structure

- ▶ The character group “F3=Exit” follows the conventional structure for a function key Complete Information Sequence:
 - It is made up of four Partial Information Sequences.
(Refer to the example Example 2 on page 39 for their individual meanings.)
 - The Partial Information Sequences appear in a logical order.

Complete Information Sequences with Unconventional Structure

Example 4 illustrates complete information sequences with an unconventional structure.

Example 4. Complete information sequences with an unconventional structure

- ▶ The character group “F3=Exit” conveys the same information as “F3=Exit” despite the fact that it is missing the Partial Information Sequence “=”.
“F3Exit” is a Complete Information Sequence with an unconventional structure.
The character group “F3=Exit”
conveys the same information as “F3=Exit” despite the fact that the Partial Information Sequences are in an unconventional order.
“Exit=F3” is a Complete Information Sequence with an unconventional structure.

Note: Modifying the KnowledgeBase to handle the above situations automatically makes their unconventional structure conventional.

Character Groups Not Complete Information Sequences

A character group that conveys no information, despite being similar to the conventional structure of some Complete Information Sequences, is **not** a Complete Information Sequence.

The character group “F10=” conveys no information. The character group is not a Complete Information Sequence.

Complete Sequences: Key to the KnowledgeBase

A rule-based KnowledgeBase is possible because of the standardization that exists in both host and GUI systems.

There are two aspects to this standardization:

- Host Complete Information Sequences have conventional structures.
- Complete Information Sequences have conventional representations in GUI systems. Informationally equivalent Complete Information Sequences have identical representations.

The first of these points is the key to a KnowledgeBase. The conventional structure makes possible automatic recognition of host Complete Information Sequences.

Once the Complete Information Sequence is recognized, it is a straightforward process to add its conventional representation to the GUI. Similarly, the functionality of any associated task can be attached to the representation without difficulty.

Variation in Partial Information Sequences

What is important about Complete Information Sequences is the type of information they convey and not the form in which the information is presented.

Therefore, the conventional structure of a Complete Information Sequence includes the *type* of meaning of the component Partial Information Sequences, but **not** the specific character groups nor their specific meanings.

Examples of different Partial Information Sequences with the same type of meanings appear in the following sections.

Informationally Identical Complete Information Sequences

Example 5 illustrates complete information sequences who are informationally identical.

Two different Complete Information Sequences whose corresponding Partial Information Sequences have the same meaning are informationally identical.

Example 5. Conveying identical information

▶ The character groups “F3=Exit”, “Pf03 = exit” and “F3:Quit” are Complete Information Sequences that convey identical information, and they display conventional structure.

They are composed of different Partial Information Sequences, but the corresponding sequences have identical meanings:

Table 4. Conveying identical information - partial sequence descriptions

Partial Information Sequences:			Description
F	Pf	f	Identifies any function key.
3	03	3	Identifies the specific member of a given set.
=	/=	:	Indicates termination of identification characters.
Exit	exit	Quit	Describes the Complete Information Sequence.

The character “√” represents the space obtained from the “spacebar.”

Informational Analogous Complete Information Sequences

The conventional structure of a Complete Information Sequence is independent of the information it conveys. A Complete Information Sequence has conventional structure as long as its Partial Information Sequences have the appropriate *type* of meaning. Example 6 illustrates this.

Example 6. Conveying similar information

- ▶ The Complete Information Sequences “F1=Initial Menu”, “F3=Exit” and “F12=Previous Menu” convey similar information. They are composed of different Partial Information Sequences, but the corresponding sequences have the same *type* of meaning:

Table 5. Conveying similar information - partial sequence descriptions

Partial Information Sequence:			Description:
F	F	F	Identifies any function key.
1	3	12	Identifies the specific member of a given set.
=	=	=	Indicates termination of identification characters.
Initial Menu	Exit	Previous Menu	Describes the Complete Information Sequence.

Information Sequences, Patterns, and Hierarchy

Summary of Information Sequence Concepts:

- Character groups that convey information are called Complete Information Sequences.
- Complete Information Sequences that convey the same information have identical GUI representations.
- Complete Information Sequences that convey analogous information have similar GUI representations.
- Complete Information Sequences are composed of Partial Information Sequences whose individual meanings combine to form a unit of information.
- Complete Information Sequences have a conventional structure.
- The Partial Information Sequences that make up a conventional structure Complete Information Sequence do not have to have a specific meaning, but they must have a specific type of meaning.

Patterns

The structure of the ACE KnowledgeBase is similar to the structure of Complete Information Sequences.

The KnowledgeBase contains *Patterns*, which are rules for classifying host screen characters and character groups. A given group of host screen characters may or may not satisfy the rules of one or more KnowledgeBase Patterns.

Primary Patterns

The KnowledgeBase classifies host character groups by the information they convey. The Patterns it uses to do this are called Primary Patterns.

The Primary Patterns in the KnowledgeBase are designed to meet four requirements:

- 1 All Complete Information Sequences that convey the same information satisfy the same Primary Pattern;
- 2 Complete Information Sequences that convey analogous information **may or may not** satisfy the same Primary Pattern;
- 3 Complete Information Sequences that convey completely different information satisfy different Primary Patterns;
- 4 All the Complete Information Sequences that satisfy a given Primary Pattern convey the same or analogous information.

ACE creates the graphical interface from the Primary Patterns. Generally, each Primary Pattern is associated with one or more controls on the graphical interface.

Complete Information Sequences, Primary Patterns and Controls

A Complete Information Sequence is a specific group of host screen characters that conveys information.

Note: Primary Patterns are organization formats for groups of host screen characters. A Primary Pattern is not a Complete Information Sequence.

A group of host screen characters conveys information, and is therefore a Complete Information Sequence, whether or not there is a KnowledgeBase Primary Pattern that recognizes the sequence.

Figure 11, taken from the ACE KnowledgeBase illustrates the difference between Complete Information Sequences and Primary Patterns:

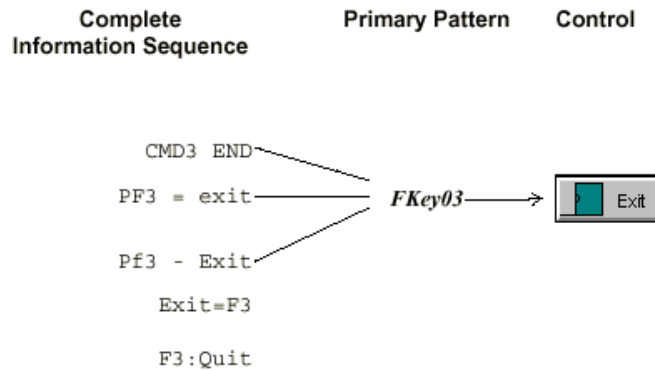

Figure 11. The difference between complete and partial sequences

Each of the five character groups listed above indicates that pressing the **F3** key causes the host to quit the current screen of the application. Therefore, all five character groups are Complete Information Sequences. Moreover, all five convey the same information.

However, only the first three character groups satisfy the KnowledgeBase Primary Pattern *FKey03*. The GUI control that represents *FKey03* is a “clickable” button.

The character groups “Exit=F3” and “F3:Quit” convey the same information as the other three groups, but they do not satisfy the Primary Pattern *FKey03*.

As all five of the above character groups convey the same information, all five should satisfy the same Primary Pattern. You modify the KnowledgeBase such that character sequences conveying the same information all satisfy the same Primary Pattern.

Accommodating Variation in the ACE KnowledgeBase

The ACE KnowledgeBase is designed so that different variations of a Complete Information Sequence are recognized by the same Primary Pattern Definition.

The KnowledgeBase recognizes variations by means of Choice-Sets and Choice-Elements:

- A **Choice-Set** is a pattern which identifies the *type* of meaning a Partial Information Sequence should have as part of a particular Complete Information Sequence.
 “OneOf”, “Character Set” and “Iteration” are Choice-Set patterns. Each of these kinds of patterns indicates that any one of a group of different Partial Information Sequences can be part of the Complete Information Sequence.
- A **Choice-Element** is a *specific* Partial Information Sequence that can be part of the Complete Information Sequence.

Table 6. Choice elements and choice sets

CHOICE ELEMENTS		CHOICE-SETS
Pattern Type	Pattern Name	
OneOf	MenuSeparator	/
		.v
		.
Character Set	BlankOrDotOrColon	/
		.
		:
Horizontal Iteration	Blank1to2	/
		//

- The character “√” represents the space produced by pressing the Spacebar key.
- “OneOf” type pattern *MenuSeparator* is a Choice-Set. A Primary Pattern containing *MenuSeparator* can be satisfied by a character group with either “√” or “.√” or “.” in the corresponding position.
- “Character Set” type pattern *BlankOrDotOrColon* is a Choice-Set. A Primary Pattern containing *BlankOrDotOrColon* can be satisfied by a character group with either “√” or “.” or “:” in the corresponding position.
- “Horizontal Iteration” type pattern *Blank1or2* is a Choice-Set. A Primary Pattern containing *Blank1or2* can be satisfied by a character group with either “√” or “√√” in the corresponding position.

A Detailed Example: Primary Pattern FKey03

Figure 12. Primary pattern FKey03

Primary Pattern **FKey03** is composed of four Choice-Set patterns: **FKeyPrefix**, **Number03**, **FKeyTerminator**, and **FKeyDescription**, with **FKeyPrefix** and **Number03** grouped together for reasons described below. These four patterns correspond to the four Partial Information Sequences described in Table 3 on page 38.

Thus, a Complete Information Sequence that satisfies **FKey03** must be a concatenation of four Partial Information Sequences. Each of the four Partial Information Sequences must be one of the Choice-Elements associated with the corresponding Choice-Set.

Note: The pattern **FKey03Name** is present because the “Accelerator” Representation Component needs to use text taken from both the **FKeyPrefix** and **Number03** patterns, and text must be taken from a single Pattern Definition.

The following subsections list the Choice-Elements associated with each of the four Choice-Sets.

FKeyPrefix

Figure 13. FKeyPrefix

Choice-Set *FKeyPrefix* is satisfied by any one of thirteen Choice-Elements:

Table 7. Choice elements and patterns for FKeyPrefix

Choice Elements	Pattern
F	FKeyPrefix1
CMD, CMd, CmD, Cmd, cMD, cMd, cmD, cmd	FKeyPrefix2
PF, Pf, pF, pf	FKeyPrefix3

Note that the patterns *FKeyPrefix2* and *FKeyPrefix3* have several character groups associated with them because of the “ignore case” option in their Pattern Definitions.

FKeyTerminator

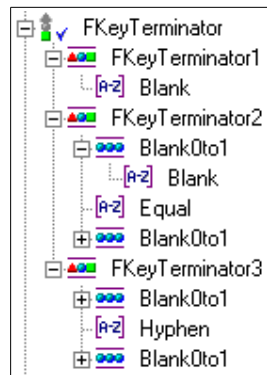

Figure 14. FKeyTerminator

Choice-Set *FKeyTerminator* is satisfied by any one of nine Choice-Elements:

Table 8. Choice elements and patterns for FKeyTerminator

Choice Elements	Pattern
/	FKeyTerminator1
=,/=, =/,/=/	FKeyTerminator2
-,/-, -/,/-	FKeyTerminator3

FKeyDescription

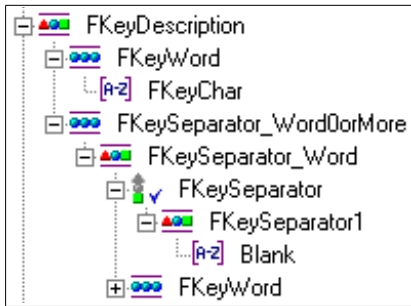

Figure 15. FKeyDescription

Choice-Set *FKeyDescription* is satisfied by any one of an essentially infinite number of Choice-Elements:

FKeyWord
FKeyWord∨*FKeyWord*
FKeyWord∨*FKeyWord*∨*FKeyWord*
 ...

Each occurrence of *FKeyWord* is itself satisfied by character groups of the form:

Abcd
 AAbcDe
 Abcd/dfdD
 ...

Thus, *FKeyDescription* is satisfied by an infinite number of Choice-Elements of the form:

Abcd
 AAbcDevAbcd
 Abcd/dfdDvAbcd

Number03

Figure 16. Number03

Choice-Set *Number03* is satisfied by two Choice-Elements: 3 and 03

Chapter 4. Modification Strategies

With this chapter the gloves come off and you begin working right inside the KnowledgeBase. All the procedures here are performed from within the KnowledgeBase Definitions window. Full details on individual steps are found in *webMethods JIS: Basic User's Guide*.

This chapter describes:

- Managing Choice-Elements Within Choice-Sets
- Modifying a “OneOf” Type Choice-Set
- Modifying a “Character Set” Type Choice-Set
- Modifying an “Iteration” Type Choice-Set
- New Pattern Definitions
- Miscellaneous New Patterns
- Priority Concepts
- Maintenance

Learning how to manage Choice-Elements within Choice-Sets is important when maintaining the modularity of the KnowledgeBase. This chapter teaches you how to modify one of character sets and iteration type pattern definitions.

You will also learn how you can use pattern definition location parameters and the priority of pattern definitions to refine the host screen analysis. In this way you make the analysis more sophisticated.

Different techniques for tweaking pattern definitions are introduced. Tips such as using the letter case, priority and position of host screen characters help you achieve a high level of control over your KnowledgeBase.

Managing Choice-Elements Within Choice-Sets

The preferred modification strategy is managing the Choice-Elements associated with a Choice-Set.

Modifying a “OneOf” Type Choice-Set

“OneOf” patterns are the entry point for the easiest kind of KnowledgeBase modification. When a “OneOf” pattern is not satisfied by a particular character group, you can create a new pattern that does recognize the character group and add the new pattern as a child pattern of the “OneOf” pattern.

Example 7. The OneOf type choice-set

"F3:Quit"

The character group above does not satisfy the Primary Pattern *FKey03* because the character group ":" is not one of the child patterns of "OneOf" pattern *FKeyTerminator*. The best solution to this situation is to make ":" a child pattern of *FKeyTerminator*.

To make ":" a child pattern of *FKeyTerminator*:

- 1 Create a Horizontal Group pattern *FKeyTerminator4* containing the Character Set pattern *Colon*.
- 2 Add *FKeyTerminator4* to the list of child patterns of *FKeyTerminator*.

The Pattern Definition tree for *FKeyTerminator* appears as follows:

Figure 17. FKeyTerminator pattern definition tree

Make the new child pattern the last pattern listed. ACE tries to apply child patterns in the order which they are listed. When you make the new child pattern the last one listed, you ensure that the new child pattern will not interfere with other character groups already recognized by the "OneOf" pattern.

Note: The ACE KnowledgeBase is designed for modification via "OneOf" patterns. This is why there are "OneOf" patterns with only a single defined possibility – where the "OneOf" serves no immediate purpose. With the "OneOf" pattern already present, you can modify the KnowledgeBase with the minimum of effort.

Modifying a "Character Set" Type Choice-Set Set

A Character Set pattern has two possible roles:

- A Character Set can contain all characters of a given type;
- A Character Set can contain all characters that serve a given purpose.

Example 8. The Character Set type choice-set

▶ The Character Set *Alpha* contains all the characters of a given type—the 26 uppercase and the 26 lowercase letters. The name “Alpha” describes the **type** of the Character Set’s characters.

The Character Set *MenuOptionChar* contains all the characters that are possible inputs to a “menu” field. The name “MenuOptionChar” describes the **purpose** of the Character Set’s characters.

These two Character Sets, *Alpha* and *MenuOptionChar* are **identical**.

The Advantage of Identical Character Sets

The advantage of identical Character Set patterns is that you can modify one of the Character Sets without affecting the other Character Set.

Example 9. Advantages of identical character sets

▶ The Character Sets *Blank* and *ColumnIgnoreChar* are identical. *Blank* contains a single character, the blank produced by pressing the spacebar. The name “Blank” describes the contents of *Blank*, which in this case is a single character.

Blank is a child pattern to many other patterns. In most of these cases the parent patterns contain *Blank* because a blank is what separates different elements of a Complete Information Sequence. Correspondingly, *Blank* separates different elements of the parent pattern.

ColumnIgnoreChar is identical to *Blank*. The name “ColumnIgnoreChar” describes the specific purpose of this Character Set pattern—which is to identify a list column that does not need to be visually represented on the GUI.

The KnowledgeBase “as is” does not need the pattern *ColumnIgnoreChar*. The pattern *Blank* could replace *ColumnIgnoreChar* without affecting either the KnowledgeBase or ACE.

The advantage of having *ColumnIgnoreChar* is that you can modify this Character Set without affecting the patterns that contain *Blank*. If your host application uses some other character to visually separate different list columns, then you can add this character to *ColumnIgnoreChar* without affecting other places where the KnowledgeBase uses the “blank” character.

Modifying a Character Set

Example 10 uses pattern *BlankOrDotOrColon* to illustrate a solution for the modification of a character set.

Example 10. BlankOrDotOrColon

- ▶ The pattern *BlankOrDotOrColon* contains the “blank” character, the “period” and the “colon.” *BlankOrDotOrColon* is used by many primary patterns as the separator pattern between a child pattern that recognizes “header text” and a child pattern that recognizes a field:

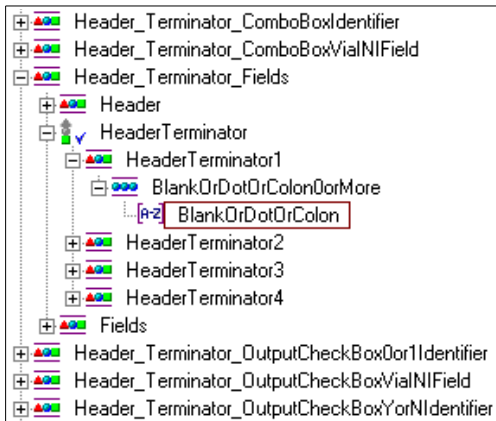

Figure 18. BlankOrDotOrColon

Suppose your host application uses an additional character, the asterisk “*”, as a separator between header text and fields. You should **not** add the “*” character to *BlankOrDotOrColon* as the name will no longer reflect the contents, and other patterns that contain *BlankOrDotOrColon* may be adversely affected.

The preferred solution is:

- 1 Create a new Character Set pattern named *BlankOrDotOrColonOrAsterisk* which includes the “blank,” the period, the colon and the asterisk.
- 2 Replace *BlankOrDotOrColon* with *BlankOrDotOrColonOrAsterisk* in those patterns that need to recognize the asterisk as a separator character.

Example 11. ComboBoxIdentifierChar

Figure 19. ComboBoxIdentifierChar character set

The pattern *ComboBoxIdentifierChar* is used to recognize a character immediately preceding a line of prompts for the allowed inputs to a field.

Suppose your host application also uses the left angle bracket "<" as a *ComboBox* identifier. You can add the "<" character to *ComboBoxIdentifierChar* without worrying that other unrelated patterns will be affected because *ComboBoxIdentifierChar* is used for a single purpose.

General Guidelines for Modifying Character Set Patterns

The guidelines are:

- A Character Set pattern whose name describes the **type** of characters it contains should **not** be modified. When such a Character Set does not handle a host screen situation, create a new Character Set and substitute it for the existing Character Set in the appropriate patterns.
- A Character Set pattern whose name describes the purpose all its characters serve **can** be modified.

You must ensure that **Separator* and **Terminator* Character Sets do not contain characters in common with the patterns they delimit.

Modifying an "Iteration" Type Choice-Set

When an Iteration pattern does not recognize a repeated host screen character group, you can replace the Iteration pattern with a new Iteration pattern.

Example 12. Modifying an Iteration

▶ "F3 = exit"

The character group above does not satisfy *FKey03* because the Iteration pattern *Blank0to1* does not recognize two successive blanks.

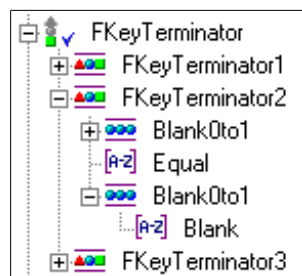

Figure 20. FKeyTerminator

A solution to this situation is to replace *Blank0to1* with *Blank0to2* which is satisfied by zero, one or two blanks.

The pattern definition tree for *FKeyTerminator* is now:

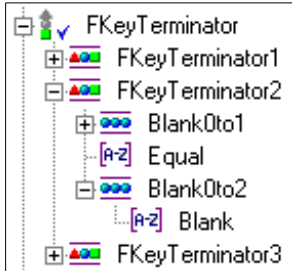

Figure 21. Modified FKeyTerminator

Case

You can use the case of characters to narrow the scope of a Pattern Definition. When a Complete Information Sequence has a definite uppercase/lowercase structure, you can use case to improve the host screen analysis.

The pattern *WindowCaptionFullScreen* is designed to recognize the host screen's title:

Figure 22. Title recognized by WindowCaptionFullScreen

and make this title the GUI's window caption:

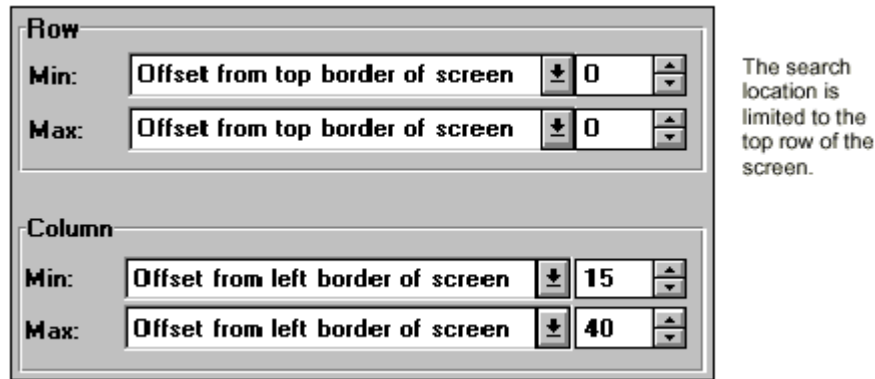

Figure 23. GUI window created by WindowCaptionFullScreen

As in the above example, the KnowledgeBase is set to search for the screen title in the top row of the screen:

The search location is limited to the top row of the screen.

Figure 24. Setting location limits

Note: The fields **Min** and **Max** of the location parameter are limits on where the Pattern Definition must begin. For example, the above parameters specify that **WindowCaptionFullScreen** must begin between columns 15 and 40, but it can extend beyond column 40.

The title may not always be in the top row of the host screen. Some of the host screens may have their titles in the second row:

Figure 25. Host screen title on the second row

This situation cannot be handled by simply allowing for the screen title to be in the second row as well as the top row. Other titles, such as the title “Sales Menu” in the example above, may be in the second row in some screens.

A general solution to this situation is described in “New Pattern Definitions” on page 59.

A simple solution to this situation can be used if the screen title’s uppercase/lowercase structure always differs from that of other titles. Suppose the screen title is always in uppercase, so that some host screens have this form:

Figure 26. Screen title in uppercase

and some host screens have this form:

Figure 27. Screen title in uppercase and on second row

In this situation, the location parameter of *WindowCaptionFullScreen* can be extended to the second row:

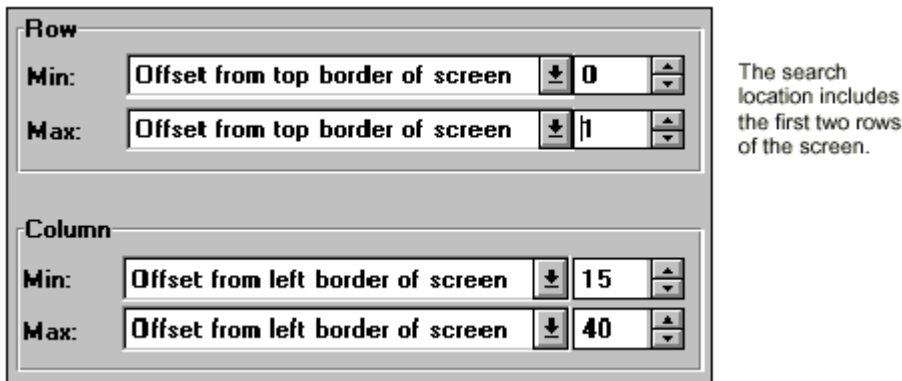

Figure 28. Extending location parameter of *WindowCaptionFullScreen*

as long as the child pattern *WindowCaptionChar*:

Figure 29. *WindowCaptionChar*

is modified to **exclude** lowercase letters:

Figure 30. Modification of *WindowCaptionChar* character set

New Pattern Definitions

You may need to create new Pattern Definitions when

- A Primary Pattern does not have the correct order or type of child patterns required to recognize an unusually structured Complete Information Sequence.
- A Primary Pattern must be included with other patterns in a new “umbrella” Primary Pattern because the original Primary Pattern cannot recognize an unusually structured Complete Information Sequence.

In both these cases you should not delete the original Primary Pattern. In the first situation the KnowledgeBase must still be able to recognize a Complete Information Sequence with the “usual” structure. In the second situation, the original Primary Pattern is a component of the new Primary Pattern.

Miscellaneous New Patterns

The KnowledgeBase is necessarily finite, so there will always be situations that can only be handled with new Pattern Definitions. The following example illustrates how a new pattern can handle a particular situation.

Example 13. Creating a new Pattern Definition

The KnowledgeBase is set to search for the screen title in the top row of the screen:

Figure 31. Screen title on the first row

This assumption may not be true for all of a host application’s screens. Some of the host screens may have their titles in the second row:

Figure 32. Screen title on the second row

This situation cannot be handled by simply allowing the screen title to be in the second row as well as the top row. Other titles, such as the title “Sales Menu” in the example above, may be in the second row in some screens.

This situation can be handled by grouping together the two Primary Patterns *WindowCaptionFullScreen* and *DefaultText* into a new “umbrella” Primary Pattern. Note that this violates the guideline that a Primary Pattern should correspond to a **single** Complete Information Sequence.

To group together *WindowCaptionFullScreen* and *DefaultText*:

- 1 Create a new Primary Pattern *WindowCaptionFullScreen_AdditionalText0to1* with the following structure:

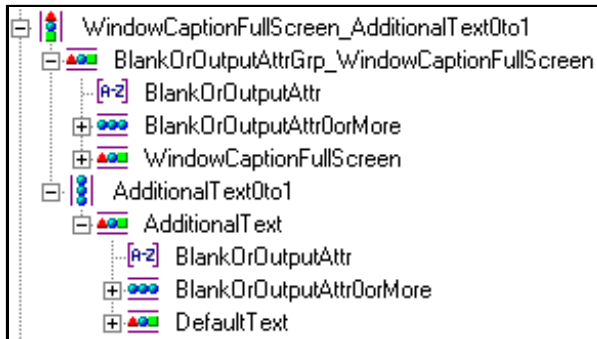

Figure 33. *WindowCaptionFullScreen_AdditionalText0to1*

The main idea of Primary Pattern

WindowCaptionFullScreen_AdditionalText0to1 is that it contains *WindowCaptionFullScreen* followed, optionally, by *DefaultText*. This means that when a row of host screen text satisfies *WindowCaptionFullScreen* a row of text immediately following will be analyzed as *DefaultText*.

The two “Blank or Output Attribute” patterns are part of *WindowCaptionFullScreen_AdditionalText0to1* because each row element of a Vertical Group pattern must start in the same column.

As in the example above, the textual part of the two rows might not, in fact, start in the same column. The “padding” with optional “Blank or Output Attributes” allows each row to start in the same column. ACE does not allow patterns to start with optional characters, so each *BlankOrOutputAttr0orMore* is preceded with *BlankOrOutputAttr*.

- 2 Set all the Location parameters for *WindowCaptionFullScreen* to “no limit.”
- 3 Set the Location parameters for *WindowCaptionFullScreen_AdditionalText0to1* to:
 - Minimum Offset from top border of Screen 0.
 - Maximum Offset from top border of Screen 1.
 - Minimum Offset from left border of Screen 14.
 - Maximum Offset from left border of Screen 39

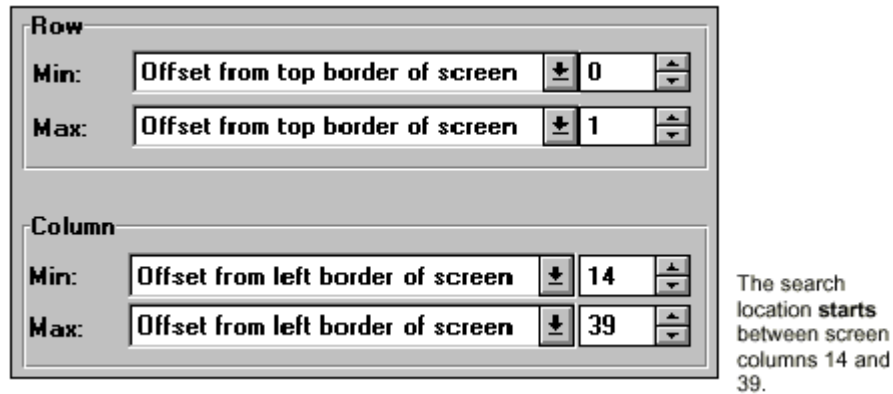

Figure 34. WindowCaptionFullScreen_AdditionalText0to1 location

The “offset from left border” parameters for WindowCaptionFullScreen were originally 15 and 40. The “offset from left border” of WindowCaptionFullScreen_AdditionalText0to1, 14 and 39, is shifted one column to the left. This shift is necessary because of the *BlankOrAttr* pattern which precedes WindowCaptionFullScreen in WindowCaptionFullScreen_AdditionalText0to1:

- A *WindowCaptionFullScreen* that starts in column 15 is preceded by *BlankOrAttr* in column 14.
 - In order for *WindowCaptionFullScreen* to start no further right than column 40, *BlankOrAttr* can be no further right than column 39.
- 4 Substitute the new pattern WindowCaptionFullScreen_AdditionalText0to1 for the pattern WindowCaptionFullScreen in Primary Section *FullScreenData*.

Priority Concepts

ACE searches for patterns according to their order. Within a screen layout section, ACE searches for the patterns according to the order that they appear in the list box.

Figure 35 shows the Section Pattern Definitions list box of the ApplytoAll Primary Section Definition dialog box.

Figure 35. Section Pattern Definitions list box

ACE searches the *ApplyToAll* section first for the *DateViaSDFField* Pattern Definition, then for the *TimeViaSDFField* Pattern Definition, etc.

This feature allows ACE to search for more specific patterns before more general patterns.

Example 14. Order of FKey patterns in Section Pattern Definitions list box

- ▶ The order of the patterns in the previous example means that ACE searches for the pattern *FKey03* before searching for the pattern *FKey*. ACE uses their relative order as follows:

The host function key *F3* is always an exit function, so Pattern Definition *FKey03* includes a fixed Representation Component:

Figure 36. Representation component of FKey03

Complete Information Sequences such as “*F3=Exit*” satisfy *FKey03* but they also satisfy the pattern *FKey*. In order for the *F3* function key to be represented by the “*Exit*” button, ACE’s analysis must match “*F3*” host character groups to the Pattern *FKey03* and not to the more general Pattern *FKey*. Therefore, ACE must search for Pattern *FKey03* before Pattern *FKey*, and so *FKey03* appears before *FKey* in the *ApplyToAll* **Section Pattern Definitions** list.

Within a *OneOf* Pattern Definition, ACE searches for the topmost child pattern first and then each of the following child patterns in sequence.

Example 15. Order of Fields patterns in Section Pattern Definitions list box

Figure 37. FieldsOneOf pattern

ACE searches first for the *PasswordField* Pattern Definition, then for the *InputFieldNumeric* Pattern Definition, etc.

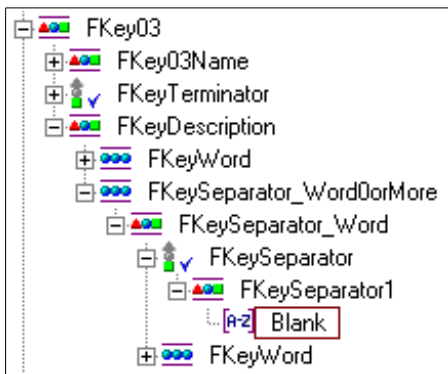

Figure 41. FKeySeparator

FKey03 must include single spaces in this way in order to correctly recognize patterns such as “F3=Quit Screen”.

To remedy this situation:

- 1 Create a new Primary Pattern, *FKey03a*, that ends with a new pattern *FKeyWord_FKeySeparator1orMore*:

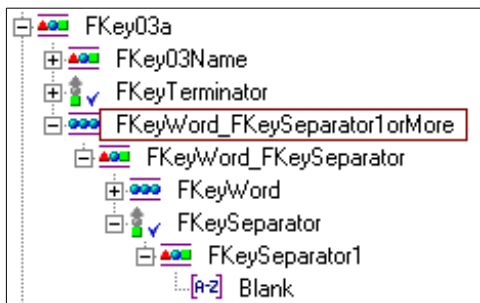

Figure 42. FKeyWord_FKeySeparator1orMore

- 2 Attach the Representation Components Button, MenuItem, Accelerator and GeneralUTMethod — each with the same parameters as they have in *FKey03* — to *FKey03a*.
- 3 Create a new Primary Pattern, *FKeya*, that ends with *FKeyWord_FKeySeparator1orMore*:

Figure 43. New pattern using FKeyWord_FKeySeparator1orMore

- 4 Add *FKey03a* to the *ApplyToAll* (Primary) Section Pattern Definitions list immediately before *FKey03*.
- 5 Add *FKeya* to the *ApplyToAll* (Primary) Section Pattern Definitions list immediately before *FKey*.

- 6 If you are using Screen Definition Files, such as DDS, add *FKey03a* and *FKeya* to the *Static Filter Section Pattern Definitions* list.

ACE will now correctly analyze the function key character groups.

Note: You must create an additional new Pattern *FKeya* so that ACE will not match “F4=Prompt F” with *FKey*. The original Patterns *FKey03* and *FKey* are still necessary because the new Patterns will not recognize character groups such as “F3=Exità” or “F18=Printà”

Maintenance

The two patterns *FKey03* and *FKey03a* recognize the same Complete Information Sequences and therefore they should have identical Representation Components. Thus, whenever you modify *FKey03* you must remember to modify *FKey03a* in the identical way.

You can ensure that both patterns will always have the same Representation Components by grouping the two Pattern Definitions under a new parent pattern and attaching all the Representation Components to this new parent pattern.

To group together *FKey03* and *FKey03a*:

- 1 Record the *Screen*, *Manager*, *Window*, *Style* and *Format* settings for each of *FKey03*'s four Representation Components.
- 2 Remove the four Representation Components from *FKey03* and from *FKey03a*.
- 3 Create a new Primary Pattern *FKey03Both* with the following structure:

Figure 44. FKey03Both

FKey03a has priority over *FKey03* because *FKey03a* is the first child pattern of *FKey03OneOf*.

- 4 Attach the four Representation Components you removed from *FKey03* to *FKey03Both* and give them the settings you recorded in *Step 1*.
- 5 Note that in the *Screen* setting you have **two** branches to light. For example, in the *Screen* setting for the *Accelerator* Representation Component you must light *FKeyName* under both *FKey03* and *FKey03a*.
- 6 Substitute *FKey03Both* for *FKey03* and *FKey03a* in the *ApplyToAll* (Primary) **Section Pattern Definitions** list.
- 7 Substitute *FKey03Both* for *FKey03* and *FKey03a* in the **Static Filter Section Pattern Definitions** list.

Chapter 5. Selected Pattern Definitions

This chapter is a guide to the specifics of modifying the KnowledgeBase. The approach taken is to present structural, functional and modification information about certain selected Pattern Definitions. While not all the Pattern Definitions are listed here, the Pattern Definitions that are listed are representative of the entire KnowledgeBase.

This chapter describes:

- An explanation of the syntax and conventions used to describe the selected Pattern Definitions.
- The individual Pattern Definitions.

Syntax and Conventions

Each pattern's description has the following format:

Figure 46. AnyChar character set

Figure 47. AnyChar

Structure

All available characters. *AnyChar*'s parent pattern, *IgnoreAny*, is the sole pattern in Primary Section *IgnoreAny*.

Purpose	The pattern <i>AnyChar</i> recognizes any character. You make use of <i>AnyChar</i> whenever you make ACE ignore characters through manually placing an <i>IgnoreAny</i> Section on them. <i>AnyChar</i> is the pattern that makes the <i>IgnoreAny</i> Section perform properly.
Partial Information Sequence	Not applicable. Any characters will be recognized.
Representation	None.
Modifications	Forbidden.

CheckBox0or1Identifier

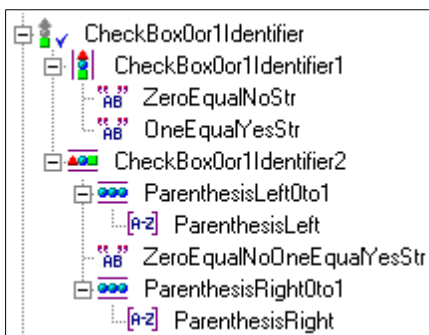

Figure 48. CheckBox0or1Identifier

Purpose	The company
Partial Information Sequence	The pattern <i>CheckBox0or1Identifier</i> is used to recognize the prompt limiting the allowed input characters of a field to "0" and "1".
	Full Details: <code>'Bààà(0=No, 1=Yes)</code>

Representation	None
Modifications	New child patterns recognizing variations of the prompt.

CheckBoxSeparator

Figure 49. CheckBoxSeparator

Purpose	The Pattern <i>CheckBoxSeparator</i> is used to recognize the boundary between an input area and the description of the allowed inputs.
Partial Information Sequence	àFull Details: 'Bààà(Y/N)
Representation	CheckBox.
Modifications	Other iterations of special characters, introduced via new child patterns.

CheckBoxVialNIField

Figure 50. CheckBoxVialNIField

Structure

The Character Set *CheckBoxViaINIChar* contains a single character:

Purpose

The Pattern *CheckBoxViaINIField* is used in conjunction with customized screen maps and the CHECKBOX.INI file to identify an input checkbox by means of a particular screen character. You use this mechanism when the host screen does not contain Yes/No or other characters that identify an input field as accepting only “yes or no.” Compare with *CheckBoxYorNIIdentifier*.

Partial Information Sequence

àFull Details: ‘^

Representation

CheckBox formatted to put “Y” or “N” in the host field.

Modifications

Change the identifier character in *CheckBoxViaINIChar*. Your application may require different inputs in the host field, such as either “0” or “1”. In this case you can change the formatting of the Representation definition, or create an entirely new Pattern Definition *CheckBox1or0ViaINIField*.

CheckBoxYorNIentifier

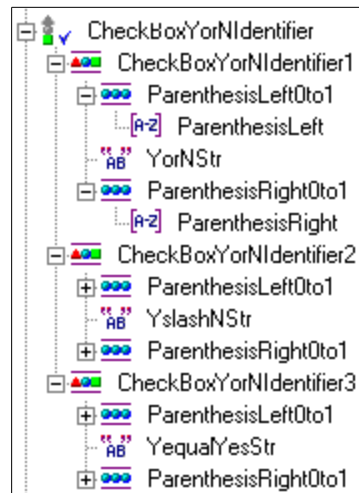

Figure 51. CheckBoxYorNIentifier

Purpose	The pattern <i>CheckBoxYorNIentifier</i> is used to recognize the prompt limiting the allowed input characters of a field to “Y” and “N”.
Partial Information Sequence	àFull Details: ‘Bààà(Y=Yes)
Representation	None
Modifications	New child patterns recognizing variations of the prompt.

ColumnCheckBoxVialNI

Figure 52. ColumnCheckBoxVialNI

Structure The Character Set *CheckBoxViaINIChar* contains a single character:

Purpose The pattern *ColumnCheckBoxViaINI* recognizes a column as a child pattern within a larger *List** pattern. It is used in conjunction with customized screen maps and the CHECKBOX.INI file to identify an input checkbox by means of a particular screen character. You use this mechanism when the host screen does not contain *Yes/No* or other characters that identify an input field as accepting only “yes or no.”

See *List_0Separator_1Header* for a discussion of the “column” aspect of patterns.

Partial Information Sequence àBBBB / ^
 àBBBB / ^
 àBBBB / ^

Representation A column of CheckBoxes.

Modifications None. You can change the identifier character in child pattern *CheckBoxViaINIChar*.

ColumnComboBoxViaINI

Figure 53. *ColumnComboBoxViaINI*

Structure The Character Set *ComboBoxViaINIChar* contains a single character:

Purpose The pattern *ColumnComboBoxViaINI* recognizes a column by its context within a larger *List** pattern. It is used in conjunction with customized screen maps and the COMBOBOX.INI file to identify an input combobox by means of a particular screen character. You use this mechanism when an input field has a limited number of allowed values, and the host screen does not contain a list of these allowed values.

See *List_0Separator_1Header* for a discussion of the “column” aspect of patterns.

Partial Information Sequence `'\àà000000à ò00000à`
`'\àà000000à ò00000à`
`'\àà000000à ò00000à`

Representation A column of ComboBoxes.

Modifications None. You can change the identifier character in child pattern *CheckBoxViaINIChar*.

ColumnHeaderTable

Figure 54. ColumnHeaderTable

Purpose The pattern *ColumnHeaderTable* refines the division of a list’s header row into “columns.” *ColumnHeaderTable* extracts the actual text to be displayed on the table buttons of the GUI from each header area defined by the hard and soft delimiters.

Partial Information Sequence `àNameààSizeà ò000à`
`àÀBBBBàà0000à ò000à`
`ÀBBBBàà0000à ò000à`
`ÀBBBBàà0000à ò000à`

Representation	None. The child patterns are represented as table buttons.
Modifications	None.

ColumnIgnore

Figure 55. ColumnIgnore

Structure The pattern *ColumnIgnoreChar* contains the character:

Purpose The pattern *ColumnIgnore* recognizes a column by its context as a child pattern of a larger *List** pattern. Host lists sometimes include a column of blanks as a way of visually separating the list's "content displaying" columns. *ColumnIgnore* is used to identify and ignore such a "separating" column.

Partial Information Sequence

```

àNameààSizeàà  à  ò000à
àÀBBBBàà0000àà  à  ò000à
 ÀBBBBàà0000àà  à  ò000à
 ÀBBBBàà0000àà  à  ò000à
  
```

Representation Variable.

Modifications None. You can add additional characters to *ColumnIgnoreChar*. Hosts often use "|" and ":" as separator characters.

ColumnInput

Figure 56. ColumnInput

Purpose	The pattern <i>ColumnInput</i> recognizes a column by its context as a child pattern of a larger <i>List*</i> pattern. It is used to identify a column of input fields.
Partial Information Sequence	à0000'BBBà à0000'BBBà à0000'BBBà
Representation	AdjustableEdit.
Modifications	None.

ColumnNumericInput

Figure 57. ColumnNumericInput

Structure The pattern *InputAttrNumeric* contains the characters:

Purpose The pattern *ColumnNumericInput* recognizes a column by its context within a larger *List** pattern. It is used to identify a column of input fields whose allowed input values must be numeric.

Partial Information Sequence	<u>à0000EBB</u> <u>à0000EBB</u> <u>à0000EBB</u>
Representation	AdjustableEdit with Ext_FloatOrInt validity check.
Modifications	None.

ColumnOutput

Figure 58. ColumnOutput

Purpose The pattern *ColumnOutput* recognizes a column by its context as a child pattern of a larger *List** pattern. It is used to identify a column of output fields.

Partial Information Sequence à0000àB
à0000àB
à0000àB

Representation Static.

Modifications None.

ComboBoxEntriesIdentifier

Figure 59. ComboBoxEntriesIdentifier

Purpose	The pattern <i>ComboBoxEntriesIdentifier</i> is used to recognize an input field and the prompt for all the allowed values of the field.
Partial Information Sequence	% Discount:à <u>'BBàà(10,20,30)à</u>
Representation	ComboBox.
Modifications	None. See child patterns.

ComboBoxIdentifier

Figure 60. ComboBoxIdentifier

Purpose	The pattern <i>ComboBoxIdentifier</i> is used to recognize an input field, and all the prompts for allowed values for the field, even if the prompts are spread over more than one line on the host.
Partial Information Sequence	àFlavor:'B(1=Vanilla, 2=Chocolate) (3=Banana, 4=Mocha)
Representation	ComboBox.
Modifications	None. See child patterns.

ComboBoxIdentifierCharacter

Figure 61. ComboBoxIdentifierCharacter character set

Purpose	The pattern <i>ComboBoxIdentifierCharacter</i> is used to recognize a character immediately preceding a line of prompts for the allowed inputs to a field.
Partial Information Sequence	àOrder By: 'Bàà(1=Number, 2=Last Name)à
Representation	None
Modifications	Additional characters.

ComboBoxIdentifierChar0orMore

Figure 62. ComboBoxIdentifierChar0orMore

Purpose	The rows of a vertical group must all start in the same column. The pattern <i>ComboBoxIdentifierCharacter0orMore</i> is used to handle the possibility that the different rows of prompts for the allowed inputs to a field start in different columns.
Partial Information Sequence	àFlavor: 'B(1=Vanilla, 2=Chocolate) _(3=Banana, 4=Mocha)
Representation	None

Modifications	None. You may want to limit the maximum number of iterations of <i>ComboBoxIdentifierChar</i> in one of <i>ComboBoxIdentifierChar0orMore</i> 's parent patterns. To do this, create a new pattern <i>ComboBoxIdentifierChar0toN</i> , that has a maximum number of iterations "N", and substitute it for <i>ComboBoxIdentifierChar0orMore</i> in the parent pattern.
----------------------	--

ComboBoxIdentifierFirstLine

Figure 63. ComboBoxIdentifierFirstLine

Purpose	The rows of a vertical group must all start in the same column. The pattern <i>ComboBoxIdentifierFirstLine</i> is used to handle the possibility that the second row of <i>EntryPairs</i> prompts for the allowed inputs to a field starts in a column to the left of the first row of prompts. The offset is often due to the fact that only the first row of prompts is preceded by an input field. The only way to vertically group the two rows is for the first row to include the input field.
Partial Information Sequence	<code>àFlavor:'B(1=Vanilla, 2=Chocolate) (3=Banana, 4=Mocha)</code>
Representation	None. See the child patterns.
Modifications	None. See the child patterns.

ComboBoxIdentifierLine

Figure 64. ComboBoxIdentifierLine

Purpose The pattern *ComboBoxIdentifierLine* is used to group together *EntryPairs* and other characters around it, so that a **vertical** iteration of, essentially, horizontal groups of *EntryPairs* can be taken together with a field into *ComboBoxIdentifier*. Without this grouping, a vertical iteration of *EntryPairs* could be recognized only if in each line on the host the *EntryPairs* were directly under one another. Further, the vertically iterated *EntryPairs* could be taken together with the field only if there were no characters between the field and the vertical iteration. See *ComboBoxIdentifier*.

Partial Information Sequence àOrder By: 'Bàà(1=Number, 2=Last Name)à

Representation None. See the child patterns.

Modifications None. See the child patterns.

ComboBoxVialNIField

Figure 65. ComboBoxVialNIField

Structure The Character Set *ComboBoxViaINIChar* contains a single character:

Purpose The Pattern *ComboBoxViaINIField* is used in conjunction with customized screen maps and the COMBOBOX.INI file to identify an input combobox by means of a particular screen character. You use this mechanism when an input field has a limited number of allowed values, but the host screen does not contain a list of these allowed values.

Partial Information Sequence àStatus:à \

Representation ComboBox.

Modifications None. Change the identifier character in *ComboBoxViaINIChar*.

ComboBoxWithIdentifierScattered

Figure 66. *ComboBoxWithIdentifierScattered*

Purpose The pattern *ComboBoxWithIdentifierScattered* is used to recognize an input field and the prompt for all the allowed values of the field, even if there are extraneous characters between the input field and the prompts. In addition there does not have to be a fixed offset between the input field and the lines of prompts. You can handle the extraneous characters independently of the characters making up the scattered group. Often you will want to ignore them via an *IgnoreAny* section.

Purpose	The pattern <i>DefaultText</i> is the lowest priority pattern in the <i>ApplyToAll</i> section. <i>DefaultText</i> is designed to ensure that all text on the screen will be recognized by a KnowledgeBase pattern.
Complete Information Sequence	Characters
Representation	Static
Modifications	None. Characters that do not need a representation are best handled by using the <i>IgnoreAny</i> or <i>IgnoreText</i> patterns.

Digit_0_0to1

Figure 68. Digit_0_0to1

Purpose	The pattern <i>Digit_0_0to1</i> is used to allow function key patterns to recognize the digits from 0 to 9 with or without a leading "0".
Partial Information Sequence	PF03=Exit
Representation	None.
Modifications	None.

DynamicFKeyGroup

Figure 69. DynamicFKeyGroup

Purpose	The pattern <i>DynamicFKeyGroup</i> is similar to <i>FKey</i> and is used to recognize function key Complete Information Sequences when the number and position of such sequences can vary in Runtime.
Complete Information Sequence	F3=Exit
Representation	Dynamic.
Modifications	You can add additional dynamic iteration patterns, such as <i>DynamicFKey03Iteration</i> to <i>DynamicFKeyGroup</i> .

DynamicListCommandIteration

Figure 70. DynamicListCommandIteration

Purpose	The pattern <i>DynamicListCommandIteration</i> is used to recognize multiple occurrences of sequences of characters satisfying <i>ListCommandArea</i> when the number and position of such sequences can vary during Runtime.
----------------	---

Partial Information Sequence	1-Update 2-Update 3-View
Representation	DynamicListCommand.
Modifications	You can add additional dynamic iteration patterns, such as <i>DynamicFKey03Iteration</i> to <i>DynamicFKeyGroup</i> .

EndOfList

Figure 71. EndOfList

Structure	Contains a dummy string. See below.
Purpose	<p>When ACE analyzes a host screen and associates a host list with a GUI table, it fixes the exact number of rows the table displays. During Runtime, there may be fewer records in the list than table rows on the GUI. The result is that the GUI table contains empty white space below the last record. The <i>EndOfList</i> pattern can sometimes be used to avoid this.</p> <p>If you know that the last line of a list is always followed by a certain character sequence, such as <code>*****End of File*****</code>, then you can set <i>EndOfList</i> to this string. When ACE detects this string during Runtime, it “knows” that the number of list records is exactly the number of rows between the start of the list and the <i>EndOfList</i> string. If this number of list records is less than the number of table rows on the GUI, ACE reduces the number of table rows, avoiding the white space. ACE adjusts the size of the table during Runtime as the number of list records changes.</p>
Partial Information Sequence	This pattern will always fail
Representation	None.

Modifications If there is an end-of-list character sequence, then substitute this sequence for the default string.

Entries

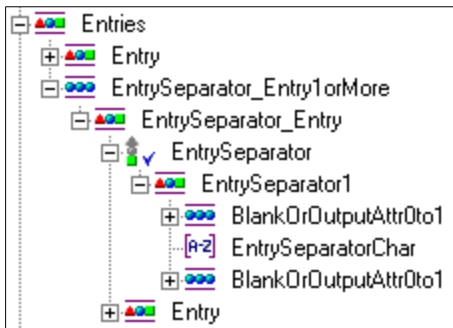

Figure 72. Entries

Purpose The pattern *Entries* is used to recognize the prompt for all the allowed values of a field.

Partial Information Sequence % Discount : à 'BBàà(10,20,30)à

Representation None. See child patterns.

Modifications None. See *Entry*

Entry

Figure 73. Entry

Structure

The Character Set *EntryChar* contains the characters:

Capital Letters:	A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
Small Letters:	a b c d e f g h i j k l m n o p q r s t u v w x y z
Digits:	1 2 3 4 5 6 7 8 9 0
Specials:	, . < (+ & ! \$ *) ; ' - / \ % _ > ? = " : # @ ~ \ ^ ` 3

Purpose

The pattern *Entry* is used to recognize a prompt for an allowed value of a field.

Partial Information Sequence

% Discount:à 'BBàà(10,20,30)à

Representation

HostBasedFormatValues, not shown on the GUI.

Modifications

None. If the allowed values for a field are other than those found in *Entry1* and *Entry2*, then *EntryChar* can be modified. *EntryChar* cannot have characters in common with *EntrySeparator* or *ParenthesisRight*. The number of iterations of *EntryChar* allowed in *Entry2* can be changed.

EntryPair

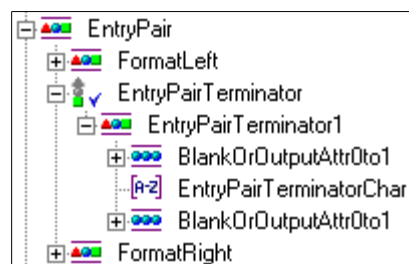

Figure 74. EntryPair

Purpose

The pattern *EntryPair* is used to recognize the complete prompt—input characters plus description—for one of the allowed inputs to a field.

Partial Information Sequence àOrder By: 'Bàà(1=Number, 2=Last Name)à

Representation HostBasedFormatItem. See the child patterns.

Modifications None. See the child patterns.

EntryPairs

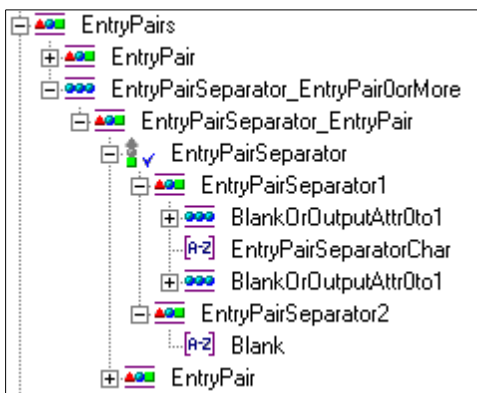

Figure 75. EntryPairs

Purpose The pattern *EntryPairs* is used to recognize a line of complete prompts—input characters plus description—for the allowed inputs to a field.

Partial Information Sequence àOrder By: 'Bàà(1=Number, 2=Last Name)à

Representation None. See the child patterns.

Modifications None. See the child patterns.

FKey

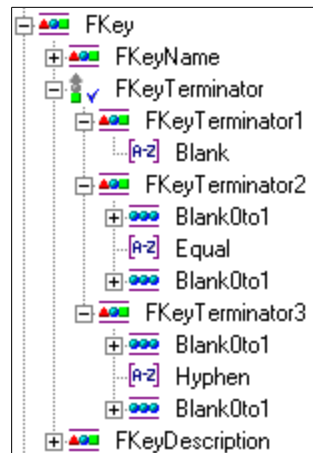

Figure 76. FKey

Purpose	The pattern <i>FKey</i> is used to recognize Complete Information Sequences that identify and describe the function of command keys.
Complete Information Sequence	Pf03=exit
Representation	MenuItem, Accelerator and GeneralUTMethod.
Modifications	None. See child patterns

FKey01

Figure 77. FKey01

Purpose	The pattern <i>FKey01</i> recognizes Complete Information Sequences describing the function of the first command key. It is used to allow the first command key to be represented by a predefined Button, in place of a PushButton that takes its text from <i>FKeyDescription</i> .
Complete Information Sequence	Pf1 = Previous Menu
Representation	PictureButton:  Cancel Menu Item; Accelerator; GeneralUTMethod.
Modifications	<i>FKey01</i> should be used “as is” only when the first command key’s function is to cancel out of the current host screen without saving any changes. If the first command key has a different fixed function, then you can attach a different picture button to <i>FKey01</i> . Any of the <i>FKey##</i> patterns can be used whenever the corresponding command key has a fixed function.

FKeyDescription

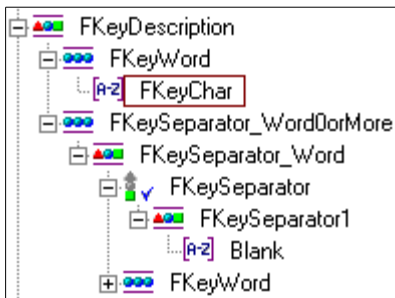

Figure 78. FKeyDescription

Structure

The Character Set *FKeyChar* contains the characters:

Capital Letters:	A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
Small Letters:	a b c d e f g h i j k l m n o p q r s t u v w x y z

Purpose

The pattern *FKeyDescription* is used to recognize the description of a command key's function.

Partial Information Sequence

F3=Exit

Representation

None. See *FKey*.

Modifications

None.

FKeyName

Figure 79. FKeyName

Purpose

The purpose of the pattern *FKeyName* is representational. *FKey*'s Accelerator representation needs the information contained in both *FKeyPrefix* and *Digit1to2*. In order for the Accelerator representation to be able to use both pieces of information, there must be a pattern that includes both *FKeyPrefix* and *Digit1to2* as child patterns—*FKeyName*.

Partial Information Sequence	Cmd03 = Quit
Representation	None
Modifications	None. See <i>FKeyPrefix</i> .

FKeyPrefix

Figure 80. FKeyPrefix

Purpose The pattern *FKeyPrefix* is used to recognize the character(s) that identify a larger sequence of characters as describing a command key's function.

Partial Information Sequence Cmd03 = Quit

Representation None.

Modifications New sequences of identifying characters can be added as additional child patterns. You can also remove the sequences that are not present in your application.

FormatLeft

Figure 81. FormatLeft

Structure

The Character Set *FormatLeftChar* contains the characters:

Capital Letters:	A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
Small Letters:	a b c d e f g h i j k l m n o p q r s t u v w x y z
Digits:	1 2 3 4 5 6 7 8 9 0
Specials:	, . < (+ & ! \$ *) ; ' - / ^ % _ > ? = : # @ ~ \ ^ 3

Purpose

The pattern *FormatLeft* is used to recognize the input segment of a prompt for the allowed inputs of a field.

Partial Information Sequence

àOrder By: 'Bàà(1=Number, 2=Last Name)à

Representation

HostBasedFormatValues (Screen Value); not shown on the GUI.

Modifications

None. *FormatLeftCharacter* can be modified, but it must not have any characters in common with *EntryPairTerminator* (see *EntryPair*) nor have any characters in common with *EntryPairSeparator* (see *EntryPairs*).

In general, delimiter patterns and the patterns being delimited cannot have characters in common.

FormatRight

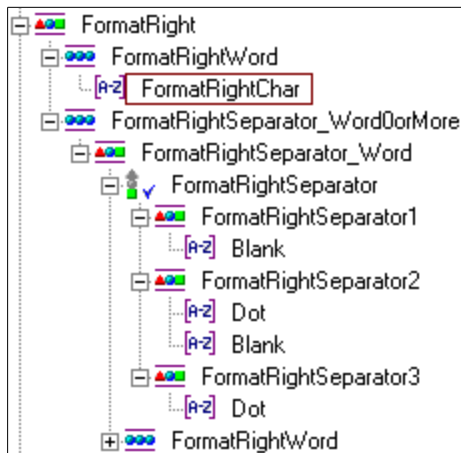

Figure 82. FormatRight

Structure

The Character Set *FormatRightChar* contains the characters:

Capital Letters:	A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
Small Letters:	a b c d e f g h i j k l m n o p q r s t u v w x y z
Digits:	1 2 3 4 5 6 7 8 9 0
Specials:	, . < (+ & ! \$ *) ; ' - / % _ > ? = " : # @ ~ \ ^ `

Purpose

The pattern *FormatRight* is used to recognize the descriptive segments of a prompt for the allowed character group inputs of a field.

Partial Information Sequence

àOrder By: 'Bàà(1=Number, 2=Last Name)à

Representation

HostBasedFormatValues (Window Value). The descriptive segments are the items in a ComboBox.

Modifications

None. *FormatRightChar* and *FormatRightSeparator* can be modified but they must not have any characters in common.

HeaderNoRD

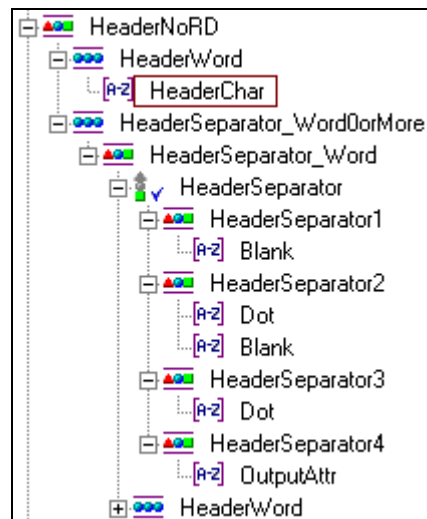

Figure 83. HeaderNoRD

Purpose	The pattern <i>IgnoreText</i> is used to recognize host screen text that should not be represented on the GUI. The supplied KnowledgeBase contains an example, <i>IgnoreText</i> , which is the Complete Information Sequence below.
Complete Information Sequence	Type options, Press Enter
Representation	Forbidden.
Modifications	None. Additional ignored texts are added as child patterns of <i>IgnoreTextOneOf</i> .

ListCertainHeader

Figure 84. ListCertainHeader

Purpose	The pattern <i>ListCertainHeader</i> is used to recognize and define strings that are always complete headers for a single column. Use this pattern to avoid problems associated with headers that are not directly above their columns and problems with header rows where the separation between individual column headers is ambiguous.
Partial Information Sequence	Change to certain header
Representation	No direct representation. Header (and other) representations are attached to other parts of <i>List*</i> Pattern definitions.
Modifications	Change the default string to an actual header string, and add additional header strings.

ListCommand

Figure 85. ListCommand

Purpose	The pattern <i>ListCommand</i> is used to recognize the prompt for input to a list row's input field, together with the meaning of the allowed input.
Partial Information Sequence	<u>S</u> -Save <u>D</u> -Delete
Representation	MenuItem. GeneralUTMethod.
Modifications	None. In child patterns.

ListCommandName

Figure 87. ListCommandName

Purpose	The pattern <i>ListCommandName</i> is used to recognize the sequences that are the possible input values to a list's input fields. The sequences are usually no more than two characters long.
Partial Information Sequence	<u>S</u> -Save <u>D</u> -Delete
Representation	Forbidden.
Modifications	None. In child patterns.

Figure 88. ListCommandNameChar

Purpose	<i>ListCommandChar</i> contains characters that are possible input values to a list's input fields.
Partial Information Sequence	<u>S</u> -Save <u>D</u> -Delete
Representation	Not Applicable.

Modifications Additional characters.

ListCommandTerminator

Figure 89. ListCommandTerminator

Purpose The pattern *ListCommandTerminator* recognizes the characters that separate between the allowed values and the description of their meanings in the prompt for the allowed values of a list's input fields.

Partial Information Sequence 1-Update 2-Delete 3-View

Representation None.

Modifications New characters can be added as child patterns. *ListCommandTerminator* cannot have characters in common with *ListCommandChar*.

ListHeadersHardDelimiter

Figure 90. ListHeadersHardDelimiter

Structure The pattern *ListHeadersHardDelimiterChar* contains the characters:

Purpose The pattern *ListHeadersHardDelimiter* contains the character sequences that ACE **always** uses to divide the header row of a list into the headers of the individual columns. Character sequences that satisfy *ListHeadersHardDelimiter* are never available to be recognized as part of a column’s header. The pattern will also typical “framing” characters from being recognized as a header sequence.

ListHeadersSoftDelimiter

Figure 91. ListHeadersSoftDelimiter

Purpose The pattern *ListHeadersSoftDelimiter* contains the character sequences that ACE optionally uses to divide the header row of a list into the headers of the individual columns. See *ListHeadersHardDelimiter*.

ListMoreIndicator

Figure 93. ListMoreIndicator

Purpose The pattern *ListMoreIndicator* is used to recognize and ignore strings that indicate that a list contains too many rows to fit onto a single screen.

Partial Information Sequence àmore...à

Representation None. No representation should be necessary.

Modifications Additional strings, for languages other than English.

ListNoSelection

Figure 94. ListNoSelection

Purpose The pattern *ListNoSelection* presents a column of list input fields as a column of the GUI Table. The pattern does not attach GeneralUTMethod *DoubleClickTable* to the Table.

The List Columns pattern *ListNoSelectionColumns* does not contain *ListLineCommand*. Thus, a column of list input fields is recognized by one of the other List Columns patterns, and the column of list input fields is represented by a Table column on the GUI.

ListNotSubfile

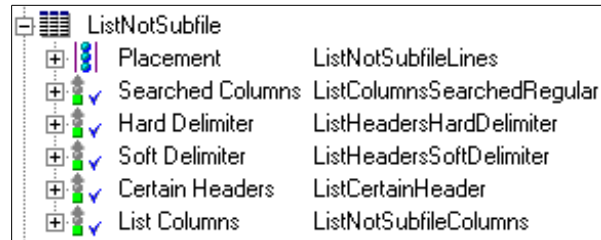

Figure 95. ListNotSubfile

Purpose

The pattern *ListNotSubfile* recognizes characters arranged into rows and columns and delimited by attributes. The pattern is used to recognize characters that are functionally lists when there is no DDS information.

When you apply the *ListNotSubfile* **section** to the host screen, you must make sure that the section does not extend beyond the list.

Structure The pattern *MenuOptionChar* contains the characters:

Capital Letters:	A B C D E F G H I J K L M N O P Q R S T U V
	W X Y Z
Small Letters:	a b c d e f g h i j k l m n o p q r s t u v
	w x y z

Purpose The pattern *Menu* is used to recognize the complete prompt—input characters plus description—for one of the allowed inputs to a menu command field.

Complete Information Sequence

Representation	PushButtons with the descriptive part of each prompt as text on the Button. GeneralUTMethod <i>SelectMenuOption</i> .
Modifications	None. See child patterns.

MenuCommand

Figure 98. MenuCommand

Purpose	The pattern <i>MenuCommand</i> is used to recognize an input field associated with a menu. Such an input field should have no direct representation on the GUI interface. The indirect representation on the interface is via the menu's PushButtons. Menu input fields are recognized by <i>MenuCommand</i> because <i>MenuCommand</i> is the only pattern containing <i>InputField</i> in the <i>Menu Primary Section</i> .
	If a second input field happens to lie within the area covered by the <i>Menu Primary Section</i> , apply an appropriate section by hand to the second input field.
Partial Information Sequence	àEnter option numberà à===>ÀBBà
Representation	A variable named "Command".
Modifications	None.

MenuDescription

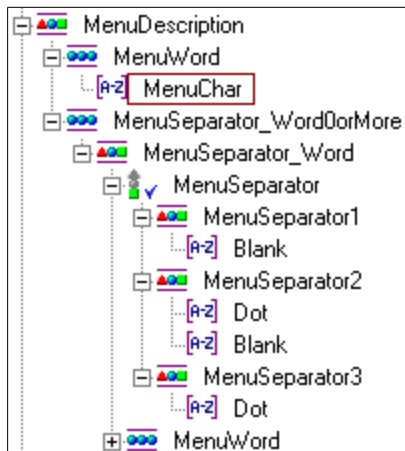

Figure 99. MenuDescription

Structure

The pattern *MenuChar* contains the characters:

Capital Letters:	A B C D E F G H I J K L M N O P Q R S T U V
Small Letters:	a b c d e f g h i j k l m n o p q r s t u v
Digits:	1 2 3 4 5 6 7 8 9 0
Specials:	., < (* & ! \$ % *) ; ' - / ^ % _ > ? = " : # @ ~ \ ^ ' 3
Input Attributes:	À Á Â Ã Ä Å Æ Ç È É Ê Ë Ì Í Î Ï Ñ Ò Ó Ô Õ Ö Ù Ú
Non Input Attributes:	Ç È Ì Í Ñ Ò Ó Ô Õ Ö Ù Ú
Null:	■

Purpose

The pattern *MenuDescription* is used to recognize the descriptive part of a prompt for the allowed inputs to a field.

Partial Information Sequence

: à 1. Manufacturing
 à 2. Finance à 3. Administration
 à 4. Distribution

Representation

None.

Modifications

None. See child patterns. *MenuChar* and *MenuSeparator* cannot have characters in common.

MessageLine

Figure 100. MessageLine

Purpose	The pattern <i>MessageLine</i> is used during Runtime Identification to recognize system messages.
Complete Information Sequence	à000000000 The sequence must be offset at least 23 rows from the top of the host screen.
Representation	None.
Modifications	Forbidden.

Not_Attr

Capital Letters:	A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
Small Letters:	a b c d e f g h i j k l m n o p q r s t u v w x y z
Digits:	1 2 3 4 5 6 7 8 9 0
Specials:	, . < (+ & ! \$ *) ; ' - / ^ % _ > ? = " : # @ ~ \ ^ ` ' `
Input Attributes:	À Á Â Ã Ä Å Æ È É Ï Î Ñ Ò Ó Ô Õ Ö Ù Ú Þ
Non Input Attributes:	Ç È É Ê Ë Ì Í Î Ï Ñ Ò Ó Ô Õ Ö Ù Ú Þ ÿ ç è é ê ë ì í î ï ñ ò ó ô õ ö ù ú þ
Null:	□

Figure 101. Not_Attr

Purpose Character Set Pattern *Not_Attr* is used to determine the extent of host screen input/output areas designated by an immediately preceding attribute character:

The field is recognized as extending until the next attribute character.

Partial Information Sequence `ÀBBBBà`

Representation None.

Modifications Forbidden.

Number01

Figure 102. Number01

Purpose The pattern *Number01* is the subpattern that limits *FKey01* to recognizing character sequences associated with the **first** command key.

Partial Information Sequence `F01=Previous Menu`

Representation None.

Modifications None. Modifications can be made to *FKeyPrefix* or *FKeyTerminator*.

OutputCheckBoxViaINIField

Figure 103. OutputCheckBoxViaINIField

Structure The Character Set *CheckBoxViaINIChar* contains a single character:

Specials: `.,<(+|&!*);'~/,%>?='`
`":#@~\^_``

Purpose The Pattern *OutputCheckBoxViaINIField* is used in conjunction with customized screen maps and the CHECKBOX.INI file to identify a protected checkbox by means of a particular screen character. You use this mechanism when the host screen does not contain Yes/No or other characters that identify an output field as displaying only “yes or no.”

Partial Information Sequence `àRead Only à``

Representation CheckBox

Modifications None. Change the identifier character in *CheckBoxViaINIChar*

OutputComboBoxIdentifierFirstLine

Figure 104. OutputComboBoxIdentifierFirstLine

Purpose	The pattern <i>OutputComboBoxIdentifierFirstLine</i> is used to allow for the possibility of more than one line of <i>EntryPairs</i> prompts on the host. The first line of prompts contains a protected field, while any following lines of prompts do not contain a field. Therefore, the <i>EntryPairs</i> in the following lines might not be aligned with the <i>EntryPairs</i> in the first line, and a vertical iteration of all the lines of <i>EntryPairs</i> is not possible.
Partial Information Sequence	<code>àOrder By:àBàà(1=Number, 2=Last <u>Name</u>)à</code>
Representation	None. Representations are attached to the child patterns.
Modifications	None. In the child patterns.

OutputComboBoxViaINIField

Figure 105. OutputComboBoxViaINIField

Structure	The Character Set <i>ComboBoxViaINIChar</i> contains a single character
------------------	---

Purpose	The Pattern <i>OutputComboBoxViaINIField</i> is used in conjunction with customized screen maps and the COMBOBOX.INI file to identify a protected combobox by means of a particular screen character. You use this mechanism when an output field has a limited number of allowed values, and the host screen does not contain a list of these allowed values.
----------------	--

Purpose	The pattern <i>SystemIDViaSDFArea</i> is the sole member of DDS filter section <i>SysName</i> . This ensures that <i>SystemIDViaSDFArea</i> is the only pattern that recognizes DDS System ID's.
Partial Information Sequence	<u>àSystemID...</u> à
Representation	None.
Modifications	None.

SystemIDViaSDFField

Figure 108. SystemIDViaSDFField

Purpose	The pattern <i>SystemIDViaSDFField</i> is the only Primary Pattern that recognizes DDS System ID's.
Complete Information Sequence	<u>àSystemID...</u> à
Representation	Variable.
Modifications	Add a GUI representation such as a Static control or a Variable.

SystemTimeOutputField

Figure 109. SystemTimeOutputField

Purpose	The pattern <i>SystemTimeOutputField</i> is used to recognize non DDS Time's by assuming that the Time output appears on the top right hand corner of host screens.
Complete Information Sequence	<u>àTime...à</u>
Representation	None.
Modifications	Change location. Add a GUI representation such as a Static control or a Variable.

SystemTimeViaSDFArea

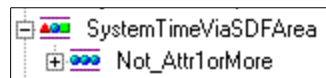

Figure 110. SystemTimeViaSDFArea

Purpose	The pattern <i>SystemTimeViaSDFArea</i> is <i>designed</i> to be the sole member of DDS filter section <i>Time</i> . This can ensure that <i>SystemTimeViaSDFArea</i> is the only pattern that recognizes DDS Time. At present, the pattern <i>IgnoreAny</i> precedes <i>SystemTimeViaSSDFArea</i> in filter section <i>Time</i> . This means that by default a DDS Time is ignored by ACE.
Partial Information Sequence	<u>àTime...à</u>
Representation	None.
Modifications	Remove <i>IgnoreAny</i> from DDS filter Section <i>Time</i> in order to activate <i>SystemTimeViaSDFArea</i> .

SystemTimeViaSDFField

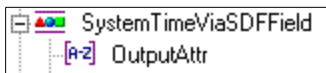

Figure 111. SystemTimeViaSDFField

Purpose	The pattern <i>SystemTimeViaSDFField</i> is <i>designed</i> to be the only Primary Pattern that recognizes DDS Time's.
Complete Information Sequence	<u>àTime...à</u>
Representation	None.
Modifications	Add a GUI representation such as a Static control or a Variable.

UserIDOutputField

Figure 112. UserIDOutputField

Purpose	The pattern <i>UserIDOutputField</i> is used to recognize non DDS UserIDs by assuming that UserIDs appear on the top left hand corner of host screens.
Complete Information Sequence	<u>àUserID...à</u>
Representation	Variable.
Modifications	Change location. Add a GUI representation such as a Static control or a MenuItem/MsgBox combination.

UserIDViaSDFArea

Figure 113. UserIDViaSDFArea

Purpose	The pattern <i>UserIDViaSDFArea</i> is the sole member of DDS filter section <i>User</i> . This ensures that <i>UserIDViaSDFArea</i> is the only pattern that recognizes DDS User ID's.
Partial Information Sequence	<u>àUserID...</u> à
Representation	None.
Modifications	None.

UserIDViaSDFField

Figure 114. UserIDViaSDFField

Purpose	The pattern <i>UserIDViaSDFField</i> is the only Primary Pattern that recognizes DDS User ID's.
Complete Information Sequence	<u>àUserID...</u> à
Representation	Variable.
Modifications	Add a GUI representation such as a Static control or a MenuItem/MsgBox combination.
