

Scalar Expressions

$$\left\{ \begin{array}{ccc} & \left[\begin{array}{c} + \\ - \end{array} \right] & \left\{ \begin{array}{c} \textit{factor} \\ (\textit{scalar-expression}) \end{array} \right\} \\ \textit{scalar-expression} & \textit{scalar-operator} & \textit{scalar-expression} \end{array} \right\}$$

This chapter covers the following topics:

- Scalar Expression
 - Scalar Operator
 - Factor
-

Scalar Expression

A *scalar-expression* consists of a factor or other scalar expressions including scalar operators.

Concerning reference priority, scalar expressions behave as follows:

- When a non-qualified variable name is specified in a scalar expression, the first approach is to resolve the variable name as column name of the referenced table.
- If no column with the specified name is available in the referenced table, Natural tries to resolve this variable as a Natural user-defined variable (host variable).

Scalar Operator

$$\left\{ \begin{array}{c} + \\ - \\ * \\ / \\ | | \\ \text{CONCAT} \end{array} \right\}$$

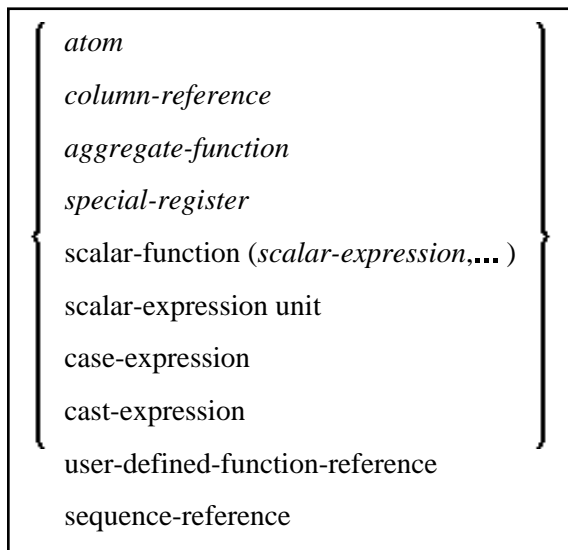

A *scalar-operator* can be any of the operators listed above; the minus (-) and slash (/) operators must be separated by at least one blank from preceding operators.

Factor

Common Set Syntax:

Extended Set Syntax:

A *factor* can consist of one of the items listed in the above diagram and described in the text below.

Atom

An *atom* can be either a *parameter* or a *constant*; see also the section *Basic Syntactical Items*.

Column Reference

A *column-reference* is a column name optionally qualified by either a *table-name* or a *correlation-name* (see also the section *Basic Syntactical Items*). Qualified names are often clearer than unqualified names and sometimes they are essential.

Note:

A table name in this context must not be qualified explicitly with an authorization identifier. Use a correlation name instead if you need a qualified table name.

If a column is referenced by a *table-name* or *correlation-name*, it must be contained in the corresponding table. If neither a *table-name* nor a *correlation-name* is specified, the respective column must be in one of the tables specified in the FROM clause.

Aggregate Function

Common Set Syntax:

COUNT	{ (*) }
	{ (DISTINCT <i>column-reference</i>) }
AVG	{ ([ALL] <i>scalar-expression</i>) }
MAX	
MIN	
SUM	

Extended Set Syntax:

COUNT	{ (*) }
	{ (DISTINCT <i>column-reference</i>) }
AVG	{ ([ALL] <i>scalar-expression</i>) }
MAX	
MIN	
SUM	
COUNT_BIG	
STDDEV	
STDDEV_POP	
STDDEV_SAMP	
VAR	
VAR_POP	
VAR_SAMP	
VARIANCE	
VARIANCE_SAMP	

SQL provides a number of special functions to enhance its basic retrieval power. The so-called SQL aggregate functions currently available and supported by Natural are:

AVG	gives the average of the values in a column
COUNT	gives the number of values in a column
MAX	gives the highest value in a column
MIN	gives the lowest value in a column
SUM	gives the sum of the values in a column

Apart from `COUNT (*)`, each of these functions operates on the collection of scalar values in an argument (that is, a single column or a *scalar-expression*) and produces a scalar value as its result.

Example:

```
DEFINE DATA LOCAL
1  AVGAGE      (I2)
END-DEFINE
...
SELECT AVG (AGE)
      INTO AVGAGE
      FROM SQL-PERSONNEL
...

```

In general, the argument can optionally be preceded by the keyword `DISTINCT` to eliminate redundant duplicate values before the function is applied.

If `DISTINCT` is specified, the argument must be the name of a single column; if `DISTINCT` is omitted, the argument can consist of a general *scalar-expression*.

`DISTINCT` is not allowed with the special function `COUNT (*)`, which is provided to count all rows without eliminating any duplicates.

Special Register

Common Set Syntax:

USER

Extended Set Syntax:

USER
CURRENT TIMEZONE
CURRENT DATE
CURRENT TIME
CURRENT TIMESTAMP
CURRENT SQLID
CURRENT PACKAGESET
CURRENT SERVER

A reference to a *special-register* returns a scalar value.

With the exception of USER, *special-registers* do not conform to standard SQL and are therefore supported by the Natural SQL Extended Set only.

Scalar Function

A *scalar-function* is a built-in function that can be used in the construction of scalar computational expressions.

For information on the scalar-functions that are supported by the Natural SQL Extended Set, see Natural SQL Statements - Syntactical Items, *scalar-function* in the Natural for DB2 documentation.

Scalar Expression Unit

YEAR
YEARS
MONTH
MONTHS
DAY
DAYS
HOUR
HOURS
MINUTE
MINUTES
SECOND
SECONDS
MICROSECOND
MICROSECONDS

unit does not conform to standard SQL and is therefore supported by the Natural SQL Extended Set only.

Case Expression

$\text{CASE } \left\{ \begin{array}{l} \textit{searched-when-clause} \dots \\ \textit{simple-when-clause} \end{array} \right\} \left[\text{ELSE } \left\{ \begin{array}{l} \text{NULL} \\ \textit{scalar-expression} \end{array} \right\} \right] \text{END}$
--

A *case-expression* does not conform to standard SQL and is therefore supported by the Natural SQL Extended Set only.

Searched WHEN Clause

$\text{WHEN } \textit{search-condition} \text{ THEN } \left\{ \begin{array}{l} \text{NULL} \\ \textit{scalar-expression} \end{array} \right\}$
--

A Searched When Clause does not conform to standard SQL and is therefore supported by the Natural SQL Extended Set only.

See details on *search-condition*.

Simple WHEN Clause

$\textit{scalar-expression} \left\{ \text{WHEN } \textit{scalar-expression} \text{ THEN } \left\{ \begin{array}{l} \text{NULL} \\ \textit{scalar-expression} \end{array} \right\} \right\} \dots$

A Simple When Clause does not conform to standard SQL and is therefore supported by the Natural SQL Extended Set only.

Cast Expression

$\text{CAST } (\textit{scalar-expression} \text{ AS } \textit{data-type})$
--

A CAST expression does not conform to standard SQL and is therefore supported by the Natural SQL Extended Set only.

User-Defined Function Reference

The option *user-defined-function-reference* belongs to the Natural SQL Extended Set. This options allows you to invoke any user-defined function. Arguments have to be placed in brackets and separated by commas. The user-defined function must be declared in the target RDBMS.

Sequence Reference

$\text{NEXT VALUE FOR } \textit{sequence-name}$ $\text{PREVIOUS VALUE FOR } \textit{sequence-name}$

The option *sequence-reference* belongs to the Natural SQL Extended Set.

This option allows you to reference the next value or the previous value of a sequence object. The sequence object has to be created in the target RDBMS before it could be referenced at runtime.

Scalar Fullselect

<i>(fullselect)</i>

The option *scalar-fullselect* belongs to the Natural SQL Extended Set.

A *scalar-fullselect* as supported in an expression is a *fullselect* - enclosed in parentheses - that returns a single row consisting of a single column value. If the *fullselect* does not return a row, the result of the expression is the null value. If more than one row is to be returned for a *scalar-fullselect*, an error occurs.
