Scalar Expressions Scalar Expressions

Scalar Expressions

```
 \left\{ \begin{bmatrix} + \\ - \end{bmatrix} \left\{ \begin{array}{l} \textit{factor} \\ \textit{(scalar-expression)} \end{array} \right\} \\ \textit{scalar-expression scalar-operator scalar-expression} \end{array} \right\}
```

This chapter covers the following topics:

- Scalar Expression
- Scalar Operator
- Factor

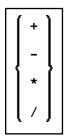

Scalar Expression

A scalar-expression consists of a factor or other scalar expressions including scalar operators.

Concerning reference priority, scalar expressions behave as follows:

- When a non-qualified variable name is specified in a scalar expression, the first approach is to resolve the variable name as column name of the referenced table.
- If no column with the specified name is available in the referenced table, Natural tries to resolve this variable as a Natural user-defined variable (host variable).

Scalar Operator

A scalar-operator can be any of the operators listed above; the minus (-) and slash (/) operators must be separated by at least one blank from preceding operators.

Factor

Scalar Expressions Atom

```
atom
column-reference
aggregate-function
special-register
```

A factor can consist of one of the items listed in the above diagram and described in the text below.

Atom

An *atom* can be either a *parameter* or a *constant* (as described in the section *Basic Syntactical Items*).

Column Reference

```
      table-name.
      column-name

      correlation-name.
```

A column-reference is a column name optionally qualified by either a table-name or a correlation-name (see also the section Basic Syntactical Items). Qualified names are often clearer than unqualified names and sometimes they are essential.

Note:

A table name in this context must not be qualified explicitly with an authorization identifier. Use a correlation name instead if you need a qualified table name.

If a column is referenced by a table-name or correlation-name, it must be contained in the corresponding table. If neither a table-name nor a correlation-name is specified, the respective column must be in one of the tables specified in the FROM clause (see *Table Expression*).

Aggregate Function

```
COUNT { (*)
    (DISTINCT column-reference) }

{ AVG MAX MIN SUM } { (DISTINCT column-reference) } ([ALL] scalar-expression)
```

Special Register Scalar Expressions

SQL provides a number of special functions to enhance its basic retrieval power. The so-called SQL aggregate functions currently available and supported by Natural are:

AVG	gives the average of the values in a column
COUNT	gives the number of values in a column
MAX	gives the highest value in a column
MIN	gives the lowest value in a column
SUM	gives the sum of the values in a column

Apart from COUNT(*), each of these functions operates on the collection of scalar values in an argument (that is, a single column or a scalar-expression) and produces a scalar value as its result.

Example:

```
DEFINE DATA LOCAL

1 AVGAGE (I2)
END-DEFINE
...
SELECT AVG (AGE)
INTO AVGAGE
FROM SQL-PERSONNEL
```

In general, the argument can optionally be preceded by the keyword DISTINCT to eliminate redundant duplicate values before the function is applied.

If DISTINCT is specified, the argument must be the name of a single column; if DISTINCT is omitted, the argument can consist of a general scalar-expression.

DISTINCT is not allowed with the special function COUNT(*), which is provided to count all rows without eliminating any duplicates.

Special Register

A reference to a special-register returns a scalar value.
