Preface

This documentation describes the Ajax Developer tools that are available in the Eclipse environment for creating and maintaining complex graphical user interfaces. It is organized under the following headings:

Getting Started with Ajax Developer	About the runtime environment. How to enable Ajax Developer for a project and how to create user interface components (that is, the folders containing the layouts). An overview of the files and folders that need to be checked in when using a version control system.
Layout Painter	How to define page layouts with the Layout Painter. This also includes the tools which are available when the Layout Painter is active: Code Assistant, Literal Assistant, Validation Rules Editor and Formula Editor.
Language Manager	How to define additional languages.
Literal Translator	How to translate text IDs.
Style Sheet Editor	How to create style sheets.
Control Editor	How to build your own controls.
Tracing	How to test the performance of a web application.
Monitoring	How to monitor the sessions that are currently running.
Server Logs Viewer	How to use the server logs viewer.

Notes:

1. For information on how to install the Ajax Developer plug-in in Eclipse, see *Installing Ajax Developer* in the *Installation* documentation.
2. For information on the Conversion Rules tool and the Conversion Logs tool, see the *Natural for Ajax* documentation that is provided for NaturalONE.

I Getting Started with Ajax Developer

1 Getting Started with Ajax Developer

▪ About the Runtime Environment	4
▪ Setting the Ajax Developer Preferences	4
▪ Working with Projects	6
▪ Working with User Interface Components	10
▪ Working With Version Control Systems	19
▪ Using the Ajax Developer Perspective	20
▪ Developing Java Extensions	21

About the Runtime Environment

Ajax Developer requires a web container such as Tomcat as its runtime environment.

If NaturalONE is installed, an Apache Tomcat is already included and all required configuration has automatically been done. In this case, you can immediately enable a project for Ajax Developer (see below).

If NaturalONE is not installed, you must first enter the settings for your own local web container environment in the Ajax Developer preferences. For further information, see [Setting the Ajax Developer Preferences](#).

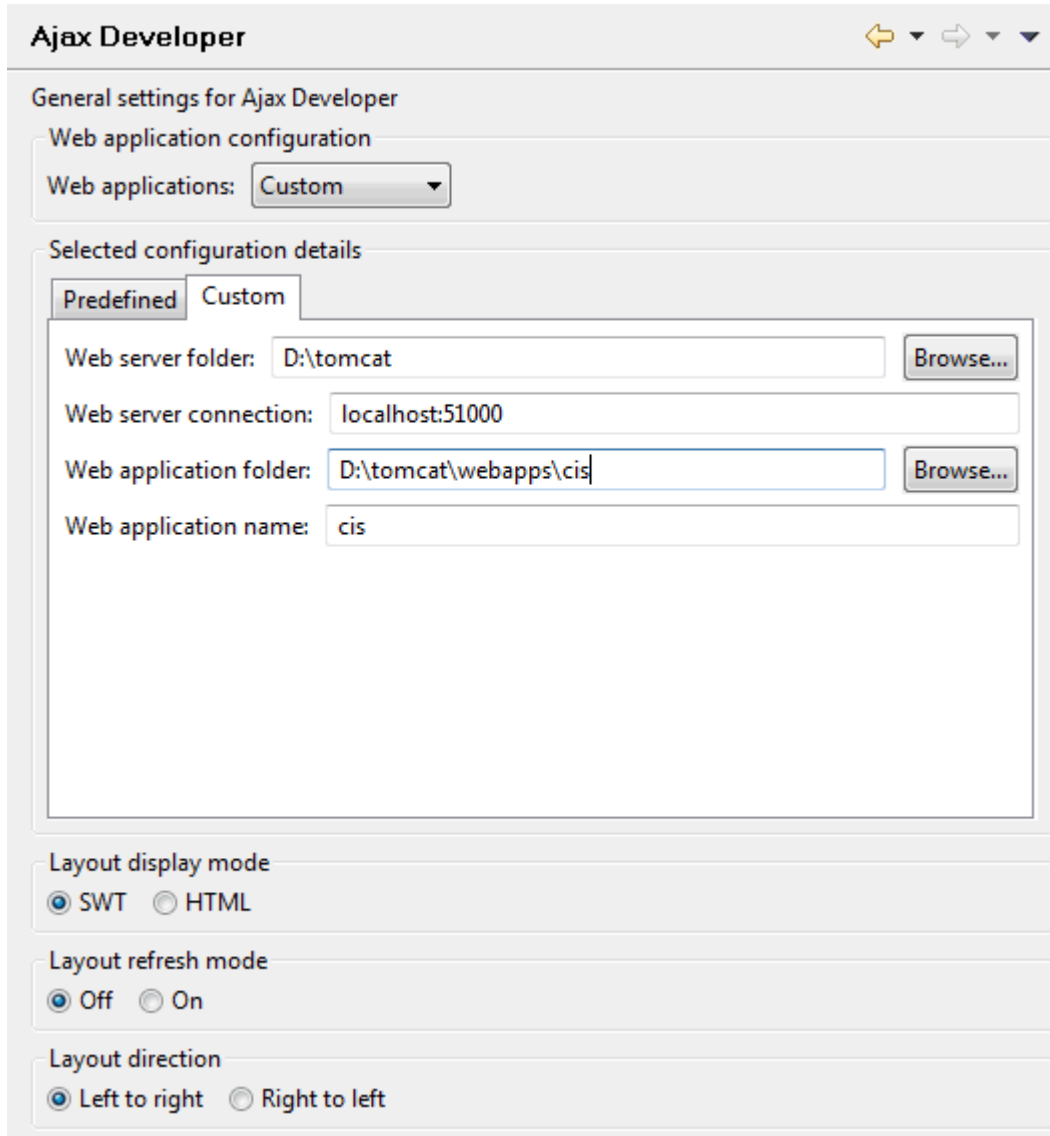

Setting the Ajax Developer Preferences

The web application configuration in the Ajax Developer preferences is normally only required if you use your own local web container environment, that is, when NaturalONE is not installed.

▶ To set the Ajax Developer preferences

- 1 From the **Window** menu, choose **Preferences**.
- 2 In the tree of the resulting dialog box, expand the **Software AG** node and then select the **Ajax Developer** node.
- 3 If you want to use your own web container environment, choose the **Custom** tab on the resulting **Ajax Developer** page and specify all required information. For information on the available options, see [Enabling a Project for Ajax Developer](#).

It is important that you set the web application folder to `<webcontainer-installdir>/webapps/cis`. Example:

- 4 The options under **Layout display mode** allow you to control how the page layouts are rendered by default in the Layout Painter preview window. If you choose **SWT**, the layout will be rendered by default as SWT (Standard Widget Toolkit) pages, that is, with Java means. If you choose **HTML**, the layout will be rendered by default as HTML pages.

Note: You can also change the display mode directly in the Layout Painter, using a menu command. See [Changing the Display Mode](#).

- 5 The options under **Layout refresh mode** allow you to enable or disable automatic refreshing of the Layout Painter's preview area.
- 6 The options under **Layout direction** allow you to design your page layout in either left-to-right (LTR) or right-to-left (RTL) direction. The specified direction is then used in the preview area of the Layout Painter.

- 7 Choose the **OK** button to save your changes and to close the dialog box.

Working with Projects

The following topics are covered below:

- [Types of Projects](#)
- [Enabling a Project for Ajax Developer](#)
- [Changing the Ajax Developer Properties for a Project](#)
- [Disabling a Project for Ajax Developer](#)

Types of Projects

With Ajax Developer, page layouts can be developed in Natural or Java projects. You create your Natural or Java project as usual and then enable this project for Ajax Developer. When a project has been enabled for Ajax Developer, the settings for a specific web container environment are applied to the project. These settings are used to develop and run page layouts.

You can have multiple projects which are enabled for different web container environments.

In a NaturalONE installation, you will usually always enable a project for the preconfigured Tomcat environment. This is the so-called "Development" environment which is automatically installed and configured with NaturalONE.

When NaturalONE is not installed, you have the following choices for the location of your Java projects:

- Choose a project location outside the web container environment. This is recommended for development, especially for working with version control systems such as CVS or Subversion.
- Choose the web application root folder named *cis* as the project location. This is only recommended for testing and debugging layouts in a production environment or test environment.

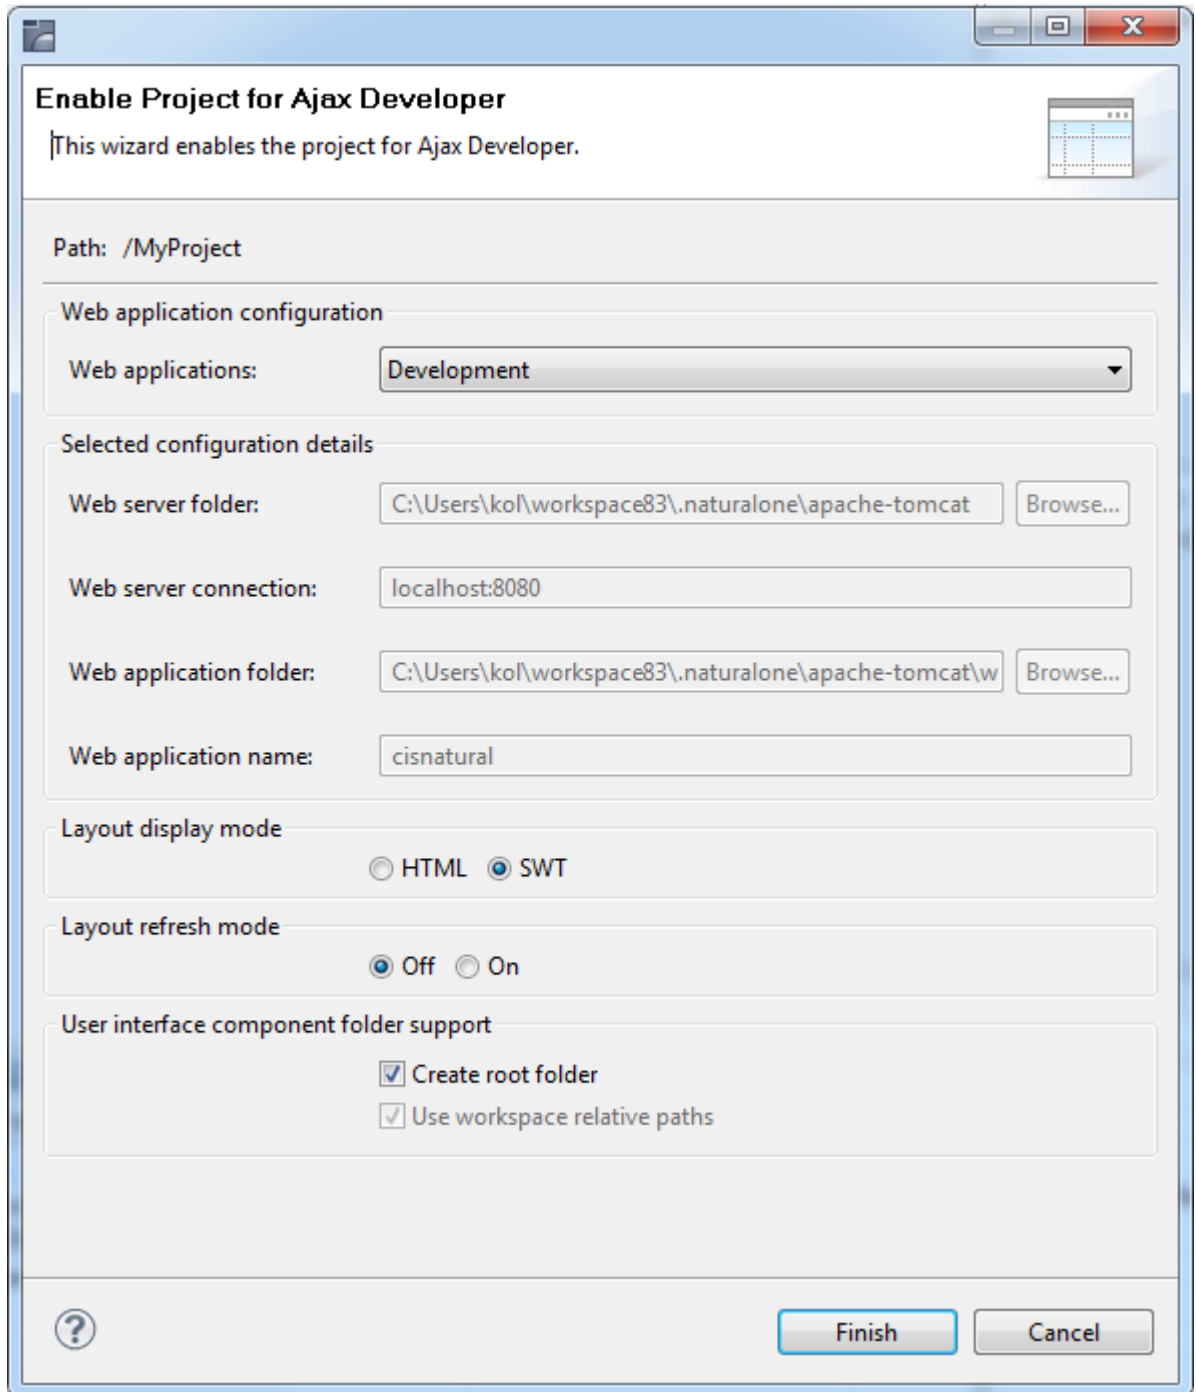

Enabling a Project for Ajax Developer

Before you can define layout pages for a project, you have to enable the project for Ajax Developer.

▶ To enable a project for Ajax Developer

- 1 In the **Navigator** view, select the project that you want to enable.
- 2 Invoke the context menu and choose **Enable for Ajax Developer**.

The following dialog box appears:

- 3 Specify the following information:

Web applications

Select one of the following options from the drop-down list box:

■ **Development**

If NaturalONE is installed, select this option. No further steps are required (the configuration options in this dialog box are disabled in this case).

Note: This option is only available when NaturalONE is installed.

■ **Custom**

If NaturalONE is not installed, select this option. In this case, the configuration options in the dialog box are enabled and you can define your own settings for your web container environment. See below.

Web server folder

The root folder of the local web container environment.

Web server connection

Host name and port number of the local web container environment.

Web application folder

The folder of the Application Designer web application. For NaturalONE installations, this is the root folder of the *cisnatural* web application. If NaturalONE is not installed, this is the root folder of the *cis* web application (`<webcontainerinstalldir>/webapps/cis`).

Web application name

For NaturalONE, this is *cisnatural*. If NaturalONE is not installed, this is *cis*.

Layout display mode

Select the display mode for the Layout Painter and Layout Tester:

■ **HTML**

This mode makes use of the ActiveX plug-in of Eclipse in which Internet Explorer is running.

■ **SWT**

This mode makes use of SWT controls which are shown in an SWT client.

Layout refresh mode

Enable or disable automatic refreshing of the Layout Painter's preview area:

■ **Off**

The preview area is not automatically refreshed when the layout is changed. It is only refreshed when the changes are saved. It is recommended that you use this mode if you are working with complex controls such as ROWTABAREA.

■ **On**

The preview area is automatically refreshed when the layout changes, even if the changes have not yet been saved.

Create root folder

When selected, all user interface components of the project are created within a folder which has the fixed name "User-Interface-Components".

When not selected, all user interface components of the project are created directly in the project directory.

When NaturalONE is installed, the default for this setting can be defined under **Window > Preferences > Software AG > Natural**.

Use workspace relative paths

This option is read-only.

In a NaturalONE installation, the **Development** web application is part of your Eclipse workspace. Ajax Developer automatically uses relative paths to access this web application. When relative paths are used, the workspace can be renamed or moved on the file system.

If you are not working with NaturalONE and you are using the **Custom** web application, the web application is usually not located within your Eclipse workspace. In this case, Ajax Developer uses absolute paths. If you move your web application or your Tomcat on the file system, you must adapt the settings.

4 Choose the **Finish** button.

The icon for the project changes to indicate that Ajax Developer has been enabled for the project.

The context menu for the project now provides the additional cascading menu **Ajax Developer** which provides for selection a number of tools which are helpful when defining layouts.

Changing the Ajax Developer Properties for a Project

If you are working with NaturalONE, you can change the layout display mode that is defined for the project, for example, from SWT mode to HTML mode. If NaturalONE is not installed, you can also change the settings for your web container environment.

To change the properties

- 1 In the **Navigator** view or in the **Natural Navigator** view, select the project which has been enabled for Ajax Developer.
- 2 Invoke the context menu and choose **Properties**.
- 3 In the tree of the resulting dialog box, select **Ajax Developer**.

The resulting page contains the same information as the dialog box which appears when you enable a project for Ajax Developer. See [Enabling a Project for Ajax Developer](#) for further information.

Disabling a Project for Ajax Developer

If you decided to **remove all user interface components** from a project, it makes sense to entirely disable this project for Ajax Developer. Then, the Ajax Developer functionality is no longer available for the project.

The user interface components are not deleted physically from the disk. Thus, it is possible to re-enable the same project for Ajax Developer later.

▶ To disable a project

- 1 In the **Navigator** view, select the project that you want to disable.
- 2 Invoke the context menu and choose **Ajax Developer > Disable**.

Working with User Interface Components

The following topics are covered below:

- [Creating User Interface Components](#)
- [File Structure in a User Interface Component](#)
- [Changing the Properties of a User Interface Component](#)
- [Exporting User Interface Components](#)
- [Removing User Interface Components](#)
- [Cleaning User Interface Components](#)
- [Building User Interface Components](#)
- [Refreshing User Interface Components](#)
- [Executing and Debugging User Interface Components](#)

Creating User Interface Components

After a project has been enabled for Ajax Developer, you can add user interface components. A user interface component is a container for a set of layout pages and additional artifacts such style sheets, images or language files.

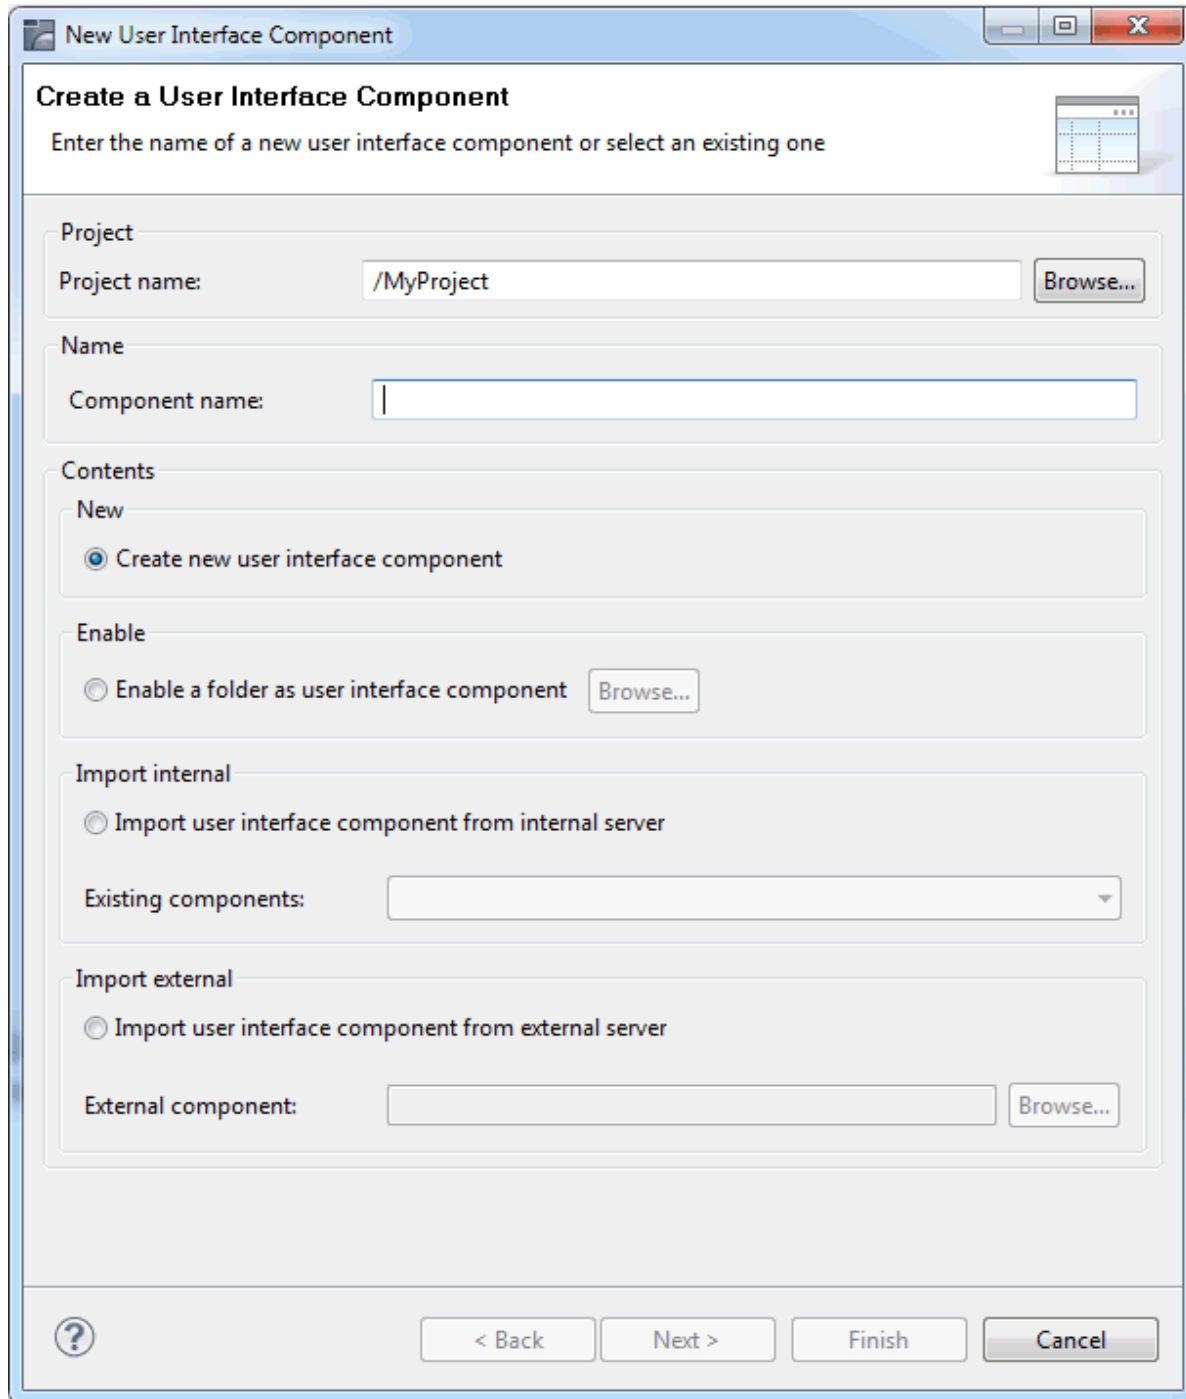

A user interface component is also connected to the corresponding Natural or Java sources which implement the business logic. A single Java or Natural project may contain several user interface components.

The name of the user interface component must be unique across the Eclipse workspace.

▶ **To create a user interface component**

- 1 In the **Navigator** view or in the **Natural Navigator** view, select the project in which you want to create a user interface component.
- 2 From the **File** menu or context menu, choose **New > User Interface Component**.

The following dialog box appears:

- 3 In the **Component name** text box, enter a name for your user interface component (for example "MyFirstUI").
- 4 Select one of the following option buttons:

Create new user interface component

This option creates a new user interface component from scratch. The location of the new user interface component is a subfolder of your Natural or Java project folder.

Enable a folder as user interface component

This option converts an existing subfolder of the project to a user interface component folder. In this case, you have to choose the **Browse** button to select the folder to be converted from a dialog box.

The internal web container environment is then used for further development.

Import user interface component from internal server

This option moves an existing Application Designer project from the internal web container environment to your Eclipse workspace. The internal web container environment is the environment configured for this Natural or Java project. In this case, you have to select a component from the **Existing components** drop-down list box.

In a NaturalONE environment, the components "njxdemos" and "njxmapconverter" are provided in the drop-down list box.

If NaturalONE is not installed, the component "cis demos" is provided, and any existing Application Designer projects in your *cis* web application. If you have chosen the *cis* web application folder as your project location, the selected Application Designer projects will not be moved. If you have chosen a different project location, the selected Application Designer projects will be physically moved to a subfolder of your Java project folder.

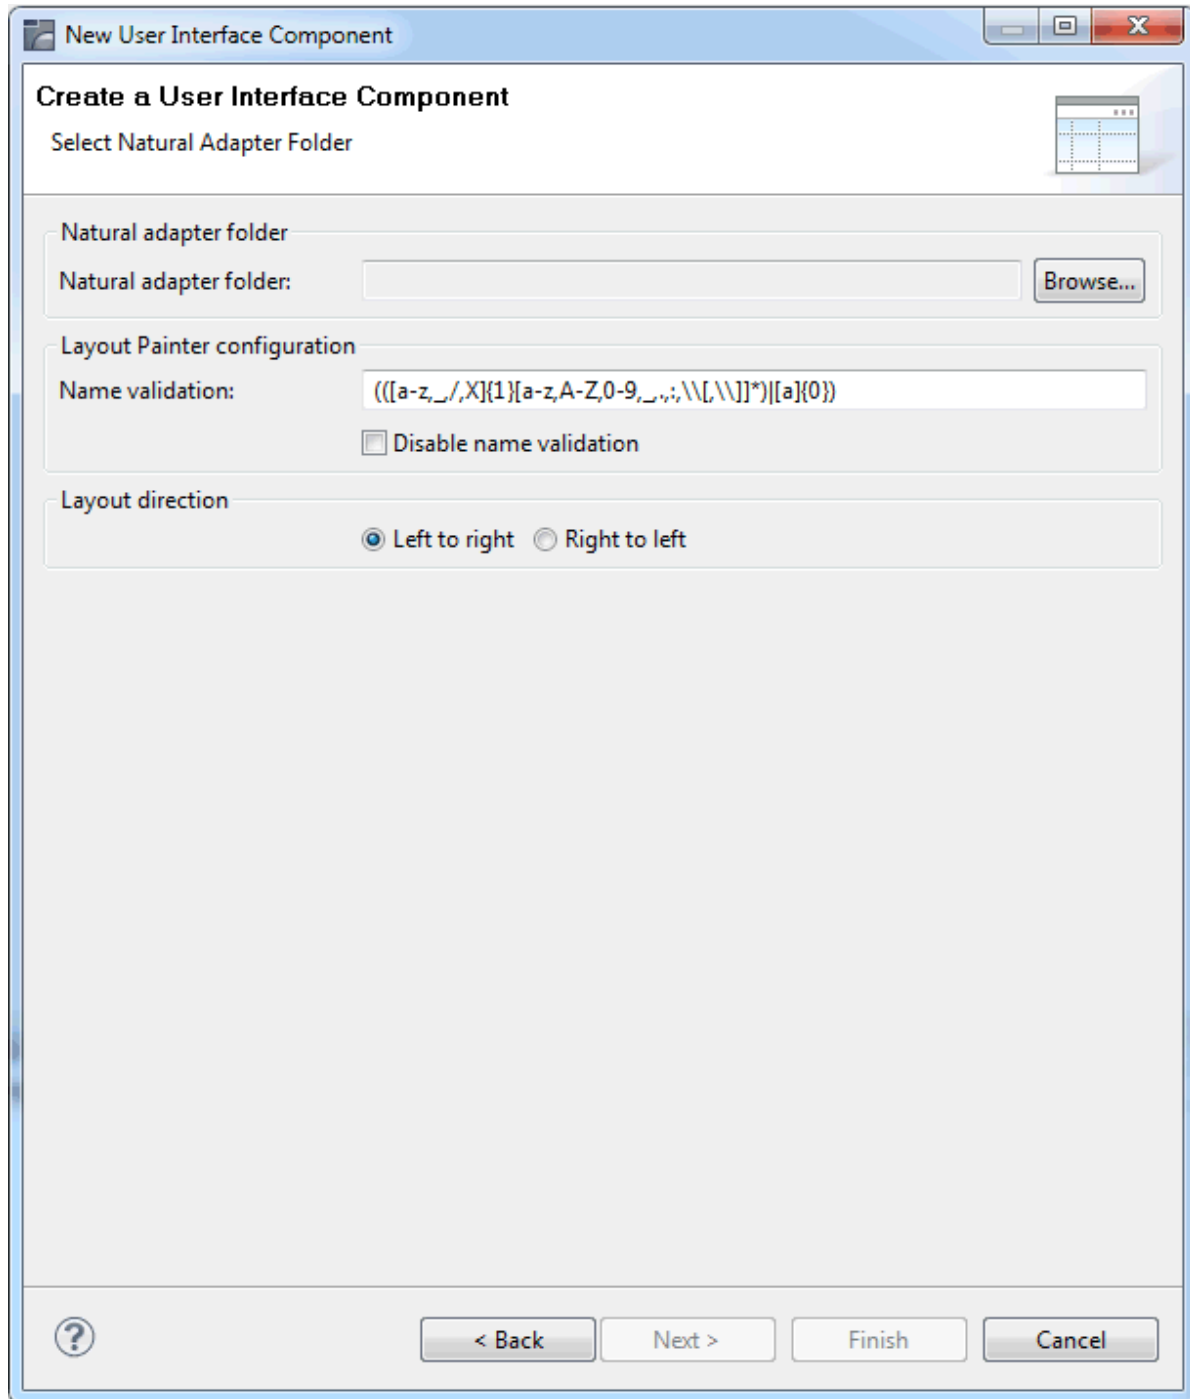

Import user interface component from external server

This option copies an existing Application Designer project from an external web container environment to your Eclipse workspace. An external web container environment is an environment other than the environment which is configured for the Natural or Java project. In this case, you have to choose the **Browse** button to select an external component from a dialog box.

The internal web container environment is then used for further development. The original sources in the external web container environment are no longer updated.

- 5 Choose the **Next** button.

The following page appears:

- 6 Choose the **Browse** button to select from a dialog box the folder into which the adapters are to be generated. Usually, you will select the *SRC* folder of a Natural library.
- 7 The **Name validation** text box shows all regular expressions that are used for the validation of properties and methods.

To switch off the validation, select the **Disable name validation** check box.

- 8 Select either the **Left to right** or **Right to left** option button. The specified layout direction is then used in the preview area of the Layout Painter. The selected layout direction applies for all layouts in this user interface component.

Note: The default layout direction for new user interface components is specified in the Ajax Developer [preferences](#).

- 9 Choose the **Finish** button.

A new folder with the component name that you have defined is now shown in the **Navigator** view or **Natural Navigator** view.

File Structure in a User Interface Component

After the creation of a user interface component, the following folders are visible in the **Navigator** view:

Folder Name	Description
<i>xml</i>	Contains the page layouts.
<i>multilanguage</i>	Contains text files for the language support. These files are maintained with the Literal Translator .

In addition, a user interface component contains folders such as *accesspath*, *wsdl* or *protocol*. These folders contain generation results which are automatically changed when a layout is modified. The files in these folders are not intended to be viewed or modified directly, and are therefore filtered in the **Navigator** view.

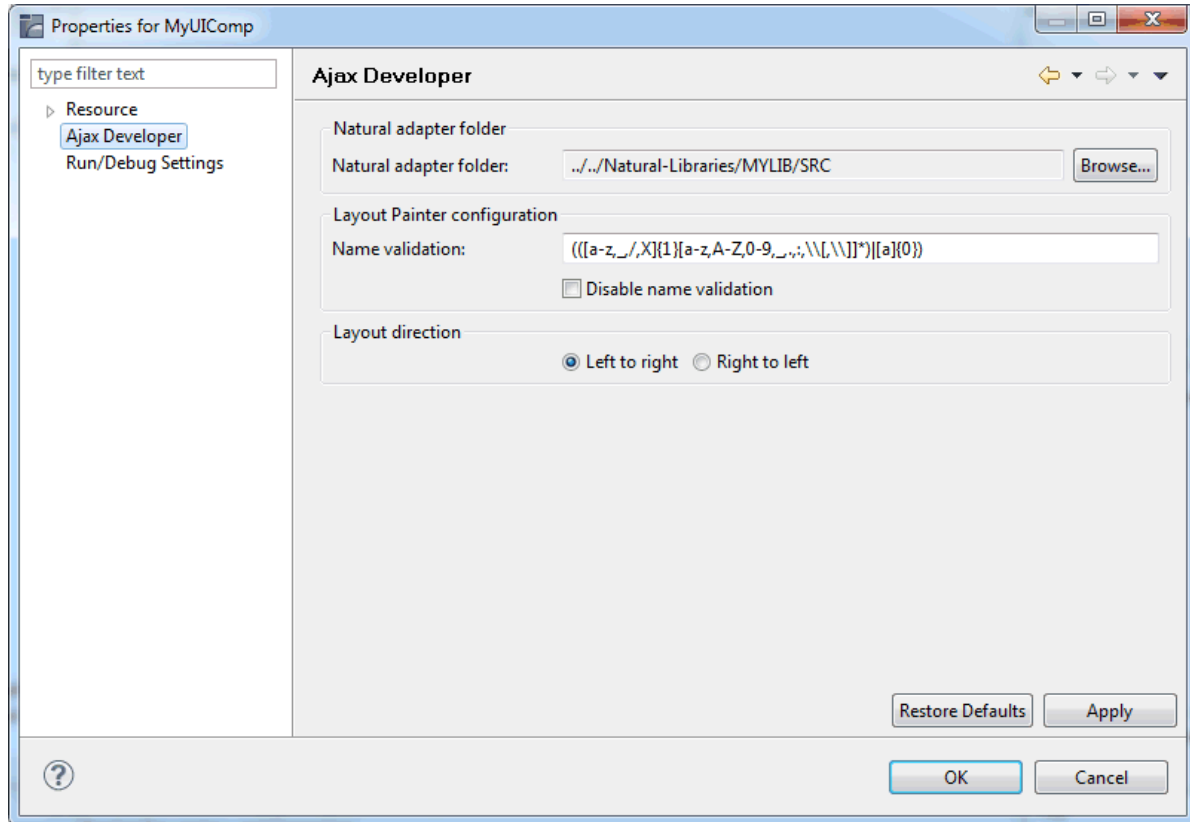

Changing the Properties of a User Interface Component

In the properties of a user interface component, you can change the path to the Natural adapter folder, you can change the regular expressions that are used for the validation of properties and methods, you can disable the name validation, or you can change the layout direction.

► To change the properties of a user interface component

- 1 Select the user interface component in the **Navigator** view or in the **Natural Navigator** view.
- 2 Invoke the context menu and choose **Properties**.
- 3 In the tree of the resulting dialog box, expand the **Ajax Developer** node.

This displays the same information which is also shown on the second page when you [create](#) a user interface component.

- 4 Change all required information.
- 5 Choose the **OK** button to save your changes and to close the dialog box.

Exporting User Interface Components

You can export a user interface component to an external web container environment. This is useful if a user interface component is to be tested in an environment other than the development environment.

▶ To export a user interface component

- 1 In the **Navigator** view, select the user interface component that you want to export
- 2 Invoke the context menu and choose **Ajax Developer > Export**.

The standard Eclipse functionality for exporting to the file system is used; see the Eclipse online help for further information.

- 3 Specify all required information.
- 4 Choose the **Finish** button.

Removing User Interface Components

When a user interface component is no longer required, you can remove it from the internal server.

After removing a user interface component, the files still exist physically on the disc and are still accessible in the **Navigator** view or **Natural Navigator** view, but the files are no longer accessible from within the web application. If you also want to delete the files, use the **Delete** command which is available in the context menu.

▶ To remove a user interface component

- 1 In the **Navigator** view, select the user interface component that you want to remove.
- 2 Invoke the context menu and choose **Ajax Developer > Remove**.

A dialog appears, indicating that the user interface component has been removed from the web application.

Cleaning User Interface Components

When you clean a user interface component, files such as **.html*, **.access* and **.NS8*, which have been generated for the layouts in the selected user interface component, are removed.

▶ To clean a user interface component

- 1 In the **Navigator** view, select the user interface component that you want to clean.
- 2 Invoke the context menu and choose **Ajax Developer > Clean**.

Building User Interface Components

When you build a user interface component, HTML files are generated for the XML layout definitions. For pages of type NATPAGE, the adapters (**.NS8* files) are also generated. This is helpful, for example, if you have previously cleaned the user interface component.

When an HTML file does not exist, it is generated. When an HTML file already exists, it is regenerated using the latest information from the XML layout definition.

Note: When you save a layout with the Layout Painter for the first time, an HTML file is automatically generated (in addition to the XML file).

▶ To build a user interface component

- 1 In the **Navigator** view, select the user interface component that you want to build.
- 2 Invoke the context menu and choose **Ajax Developer > Build**.

Refreshing User Interface Components

In rare situations, it may happen that the configuration files of the web application are not in sync with the existing user interface components in your project. This may happen, for example, when a user interface component is created in a new workspace before the initialization of the **Development** web application is finished.

In these cases, you can refresh the user interface components to synchronize the configuration files of the web application with the user interface components. If the user interface components are already in sync, the commands described below will not apply any changes.

▶ To refresh all user interface components in a project

- 1 In the **Navigator** view, select the project in which you want to refresh the user interface components.
- 2 Invoke the context menu and choose **Ajax Developer > Refresh User Interface Components**.

▶ To refresh a single user interface component

- 1 In the **Navigator** view, select the user interface component that you want to refresh.
- 2 Invoke the context menu and choose **Ajax Developer > Refresh**.

Executing and Debugging User Interface Components

You can execute pages of type PAGE and MFPAGE (workplace). Execution means that the page with the real application (Natural or Java) is started in the browser.

For workplace applications (MFPAGE) which contain pages implemented with Natural, you can debug the corresponding Natural programs.

For NaturalONE, see also *Executing and Debugging Workplace Applications* in the *Natural for Ajax* documentation that is provided for NaturalONE.

▶ To execute a page

- 1 In the **Navigator** view, select a page of type PAGE or MFPAGE.
- 2 Invoke the context menu and choose **Ajax Developer > Execute**.

▶ To debug Natural programs in a workplace application (MFPAGE)

- 1 In the **Navigator** view, select a page of type MFPAGE.
- 2 Invoke the context menu and choose **Ajax Developer > Debug**.

**Notes:**

1. For pages of type MFPAGE, the **Debug** command is only enabled when the debug attach server has been enabled in the Natural preferences. See also *Setting the Preferences in Using NaturalONE*, which is part of the NaturalONE documentation.
2. The commands **Execute** and **Debug** are only available for the above mentioned page types. For pages of type NATPAGE, you have to start the application by executing or debugging the corresponding Natural main program. See also *Executing the Main Program* and *Debugging the Main Program* in the *Natural for Ajax* documentation that is provided for NaturalONE.

Working With Version Control Systems

Eclipse provides fully integrated support for version control systems such as CVS or Subversion (SVN) via corresponding plug-ins.

The following topics are covered below:

- [Checking In Projects and User Interface Components](#)
- [Checking Out Projects and User Interface Components](#)

Checking In Projects and User Interface Components

You have to check in the following Ajax Developer-specific files and folders of a project:

- The file *com.softwareag.cis.ide.prefs* which is stored in the *.settings* directory of your project.

This file contains the Ajax Developer-specific settings for this project (for example, whether this project has a root folder for the user interface components). To be able to simply check out a project into a new workspace and be able to work with the project immediately without having to reenter any configuration settings, you have to check in this file.

- The following files in the individual user interface components:

File Type	Description
Page Layouts	The page layouts are stored in the <i>xml</i> subdirectory of your user interface component.
Translation Information	If using the standard multi language management, literal translations are stored in comma-separated files in the <i>multilanguage</i> subdirectory of your user interface component.
Help Texts	If using the standard online help management, help texts are stored in the <i>help</i> subdirectory of your user interface component.

File Type	Description
Other Web Resources	Images, style sheets or additional HTML pages are often used in user interface components. For example, your user interface component may have an <i>images</i> subdirectory which contains all GIF and JPG files.
Configuration Files	The file <i>.cisapplication</i> and, if it exists, the file <i>ciseditorconfig.xml</i> .

Do not check in the following files and folders (you can see them, for example, when you switch to the Resource perspective):

- Do not check in the **.html* and **_SWT.xml* files which are stored in the root directory of your user interface component.
- Do not check in any *ZZZZZZ** files (that is, any files which start with "ZZZZZZ"). These are temporary files that are used by the Layout Painter.
- Do not check in derived folders. Some folders of a user interface component such as *accesspath*, *wSDL* and *protocol* are marked as "derived" in the folder properties. Version control systems such as CVS and Subversion automatically ignore derived folders during check-in. This is important because these files are automatically generated when you build your project.

To ignore the first two file categories listed above, you can either add them to *.cvsignore* or *svn:ignore* (depending on the version control system you are using), or you can simply **clean the user interface component** before you synchronize with your repository.

Checking Out Projects and User Interface Components

If you have checked in all files and folders described above, you can simply check out the project, including the user interface components, into a new workspace. The user interface components are automatically added to the internal Tomcat of this workspace.

After a check-out, it is recommended that you rebuild the project using the **Clean** command from the **Project** menu. If the **Build Automatically** command in the **Project** menu is currently not active, make sure that **Start a build immediately** is switched on in the **Clean** dialog box.

Using the Ajax Developer Perspective

Ajax Developer provides its own perspective which contains the views which are important for editing layouts. The positions and sizes of the views are optimized for developing and testing the layout pages.

Note: When NaturalONE is installed, it is not mandatory to use the Ajax Developer perspective. You can also use the NaturalONE perspective. However, with the Ajax Developer perspective, the **Properties** view for modifying the properties of a page layout, for example, is shown with a convenient size and position.

▶ **To open the Ajax Developer perspective**

- From the **Window** menu, choose **Open Perspective > Ajax Developer**.

The corresponding icon is then shown on the perspective bar.

- **Note:** By clicking the corresponding icon in the perspective bar, you can quickly switch between the NaturalONE perspective and the Ajax Developer perspective.

Developing Java Extensions

For some advanced functionality such as writing adapter listeners, advanced custom controls or advanced workplace enhancements, the development of Java extensions is supported.

If you want to develop Java extensions in NaturalONE, proceed as follows:

- Enable your Natural project for Java. For detailed information on how to enable projects for Java, see the Eclipse documentation.
- Add the files *cis.jar* and *sdo.jar* to the build path of the project. These files are located in the folder *cisnatural/WEB-INF/libs*.
- Add the Javadoc location to the *cis.jar*. A corresponding zip file with the name *cisjavadoc.zip* can be found in the folder *cisnatural*.

- **Note:** The folder *cisnatural* is located in your Eclipse workspace under *\.naturalone\apache-tomcat\webapps*.

II

Layout Painter

The Layout Painter is the central tool for layout development. You use it to specify the layouts of your HTML pages. The Layout Painter includes an active WYSIWYG preview in which you can test your applications.

The description of the Layout Painter is organized under the following headings:

Getting Started with the Layout Painter

Defining the XML Layout

Using the Code Assistant

Using the Literal Assistant

Using the Validation Rules Editor

Using the Formula Editor

2 Getting Started with the Layout Painter

- General Information 26
- Creating a Layout 26
- Layout Templates 28
- Opening an Existing Layout 29
- Elements of the Layout Painter 29
- Creating Custom Layout Templates 31

General Information

Ajax Developer follows the commonly accepted paradigm of separating the layout (view) as much as possible from the application logic (model). You design the layout using the WYSIWYG Layout Painter. The result is kept in an XML page layout file. When you save the XML page layout, an HTML page is generated.

On the one hand, the XML layout contains the used controls of a page; on the other hand, it keeps information about how these controls are bound to the application code.

If you implement your application in Natural, the controls are bound to a Natural adapter. The Natural adapter is generated as soon as you save the page layout. The Natural adapter becomes part of the Natural application and forms the interface between the Natural application code and the user interface.

If you implement in Java, the controls are bound to the properties and methods of a Java adapter. This is a Java class that you can generate with the Code Assistant (which is part of the Layout Painter).

In addition, the XML layout may optionally contain so called “literals”. Literals are text identifiers (text IDs) that are replaced at runtime with language-specific texts. For each language you want to support, there must be a comma-separated value (CSV) file that contains the language-specific text per literal. You maintain these translation files using the Literal Assistant (which is part of the Layout Painter).

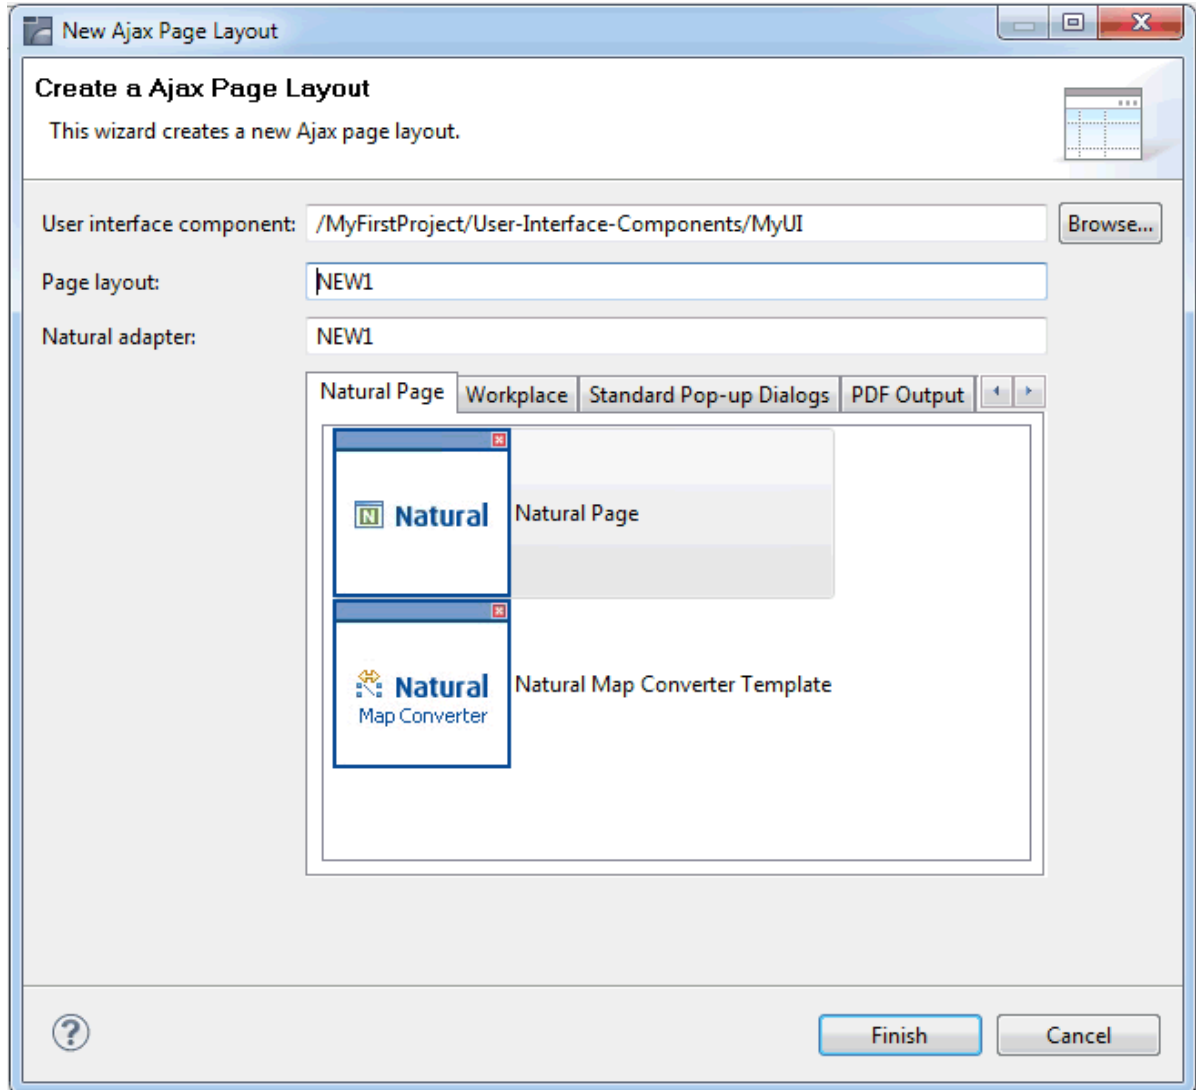

Creating a Layout

The layouts that you create as described below are stored in the *xml* folder of the user interface component.

► To create a layout

- 1 In the **Navigator** view or in the **Natural Navigator** view, select the user interface component or the *xml* folder.
- 2 From the **File** menu or context menu, choose **New > Page Layout**.

The **New Ajax Page Layout** dialog box appears, providing several tabs from which you can select a layout template.

- 3 In the **Layout page** text box, enter the name of the file that is to contain your layout definition. Do not specify an extension; the extension ".xml" will automatically be added.

The **Natural adapter** text box is only visible when the **Natural Page** tab is currently selected. Here, you enter the name of the Natural adapter that will be generated when you save the page layout. This name must match the naming conventions for Natural objects.

- 4 Select the layout template for your page. See also [Layout Templates](#).
- 5 Choose the **Finish** button.

The Layout Painter appears (see [below](#)).

Layout Templates

When you **create** a layout, you have to select a layout template in the **New Ajax Page Layout** dialog box. The following tabs, which contain different types of layout templates, are offered by default:

- **Natural Page**

The templates on this tab are used to create pages for Natural for Ajax. They have the NATPAGE control as the top node. See the NaturalONE documentation for further information.

- **Workplace**

The templates on this tab are used for arranging Application Designer pages in a frameset. They have the MFPAGE control as the top node. See *Multi Frame Pages* in *Working with Pages* for further information.

- **Standard Pop-up Dialogs**

Several standard pop-up dialogs are supported. See *Standard Pop-up Dialogs* in *Working with Pages* for further information.

These standard pop-up dialogs are also used within the workplace framework. Sometimes, you would like to slightly modify these standard pop-up dialogs, for example, when writing a workplace application. The templates on this tab are used to create a copy of the corresponding standard pop-up dialog in your project and adapt the appearance to your needs. Be sure not to change the names of the layouts, the corresponding adapter classes or the properties/methods.

- **PDF Output**

The templates on this tab are used for integrating a PDF document into an Application Designer page. They have the CISFO:FOPPAGE2 control as the top node. See *PDF and FOP Services* for further information.

- **HTML Page**

The templates on this tab have the PAGE control as the top node. See *Typical Page Layout* in *Layout Elements* for further information.

If you have created your own custom layout templates, they are also offered for selection. For further information, see [Creating Custom Layout Templates](#).

Opening an Existing Layout

Layouts are stored in the *xml* folder of the user interface component. They have the extension *.xml*.

▶ To open a layout

- In the **Navigator** view or in the **Natural Navigator** view, double-click the layout that you want to open.

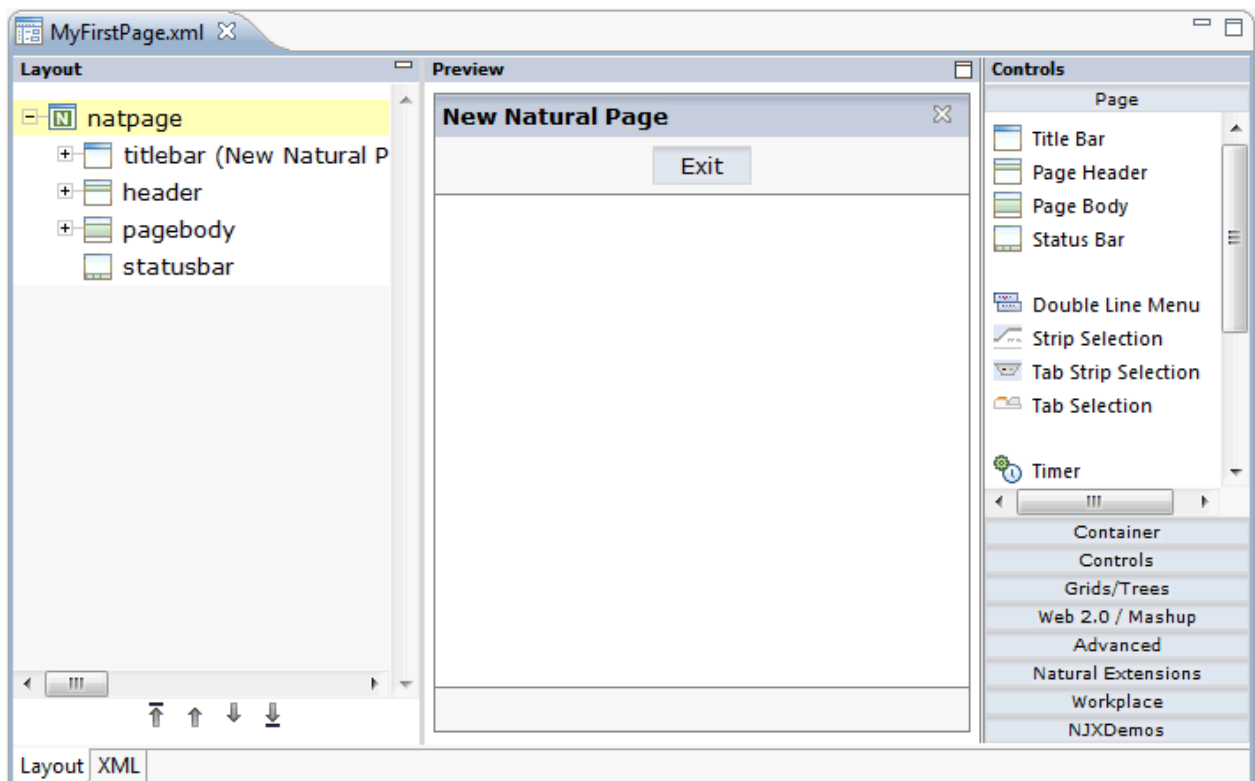

Or:

Invoke the context menu for the layout and choose **Open With > Layout Painter**

The Layout Painter appears (see [below](#)).

Elements of the Layout Painter

The Layout Painter appears when you **create** a new layout or when you **open** an existing layout.

The Layout Painter is divided into several areas:

■ **Layout Area (left side)**

This area shows the layout tree which contains the controls that represent the XML layout definition. You drag these controls from the controls palette into the layout tree. Each node in the layout tree represents an XML tag.

Using the button which is located to the right of the title bar, you can hide the layout area. This enlarges the preview area. To redisplay the layout tree, choose the small arrow which is shown in the left of the preview area's title bar.

■ **Preview Area (middle)**

The preview area shows the page which is created using the controls in the layout area. This page is refreshed each time, you choose the **Refresh Preview** command (see below).

Using the toggle button which is located to the right of the preview area's title bar, you can enlarge the preview area so that it takes up the space of the layout area and controls palette, and reduce the enlarged preview area so that the layout area and controls palette are shown again.

■ **Controls Palette (right side)**

Each control is represented by an icon. A tool tip is provided which appears when you move the mouse pointer over the control. This tool tip also displays the XML tag which will be used in the XML layout.

The controls palette is structured into sections (for example, **Page** and **Container**), where each section represents certain types of controls.

Note: The sections that are shown in the controls palette and the content of a section depend on the layout template that is used for the current layout.

When you select a control in the layout tree or in the preview area, the properties for this control are shown in the **Properties** view. You can modify the properties as required.

When the Layout Painter is active, the additional menu **Ajax Developer** is shown in the menu bar. Using this menu, you can invoke additional tools which are helpful for the creation of layouts:

■ **Code Assistant**

Only used for developing page layouts in Java. Helps you to generate code for all properties and methods which are explicitly referenced in the page layout. See [Code Assistant](#) for further information.

■ **Literal Assistant**

Helps you to prepare your layout for multiple languages. You can maintain texts of different languages for the literals that are referenced within the XML layout. See [Literal Assistant](#) for further information.

■ Validation Rules Editor

You can define that the value that is entered in a field must meet certain conditions. See [Using the Validation Rules Editor](#) for further information.

■ Formula Editor

You can define a formula for a field (for example, the sum of the fields A and B is to be shown in field C). See [Using the Formula Editor](#) for further information.

Some commands of the **Ajax Developer** menu (such as **Refresh Preview**) are also available as buttons in a toolbar.

Creating Custom Layout Templates

You can create your own custom layout templates. When you **create** a layout, your custom layout templates are offered for selection together with the default **layout templates** in the **New Ajax Page Layout** dialog box.

You can create your custom layout templates in any Natural project. Your custom layout templates can always be used from all other Natural projects in the current workspace.

 **Tip:** It is helpful to create a single project which contains all of your custom layout templates. Other developers can then import this project into their own workspaces. Thus, they can also use your custom layout templates.

▶ To create a custom layout template

- 1 In the user interface component of your project, create a folder with the name "cisconfig".

 **Note:** In the **Navigator** view, the *cisconfig* folders are hidden by default. To make these folders visible, go to the view menu of the **Navigator** view and choose **Filters**. In the resulting dialog box, deselect the **cisconfig** check box and choose the **OK** button.

- 2 In the *cisconfig* folder, create one or more layout template files. Or copy your template files into this folder.

The layout template files have the same XML format as the page layout files (for an example, see [Viewing the XML Code](#)). Therefore, you can also copy an existing layout file into the *cisconfig* folder and rename it to, for example, "editorTemplateNATPage1.xml".

- 3 In the *cisconfig* folder, create an XML configuration file with the name "editortemplates.xml". This file defines all custom layout templates that are to be used. Example:

```
<?xml version="1.0" encoding="UTF-8"?>
<editortemplates>
  <group name="Natural Page">
    <xmltemplate filename="editorTemplateNATPage1.xml"
      image="templatenatural.jpg"
      info="My Natural Page Template"/>
  </group>
</editortemplates>
```

The XML configuration file uses the following tags:

`<editortemplates>`

Each XML configuration file must have exactly one `<editortemplates>` tag.

`<group>`

You can define one or more `<group>` tags inside the `<editortemplates>` tag.

Each `<group>` tag has a mandatory `name` attribute which defines the tab in the **New Ajax Page Layout** dialog box on which the custom layout template is to be shown (see [Creating a Layout](#)).

You can also add a new tab to the **New Ajax Page Layout** dialog box by specifying a new group name (for example, "My Templates"). However, keep in mind that such a new tab is not suited for Natural pages because the text box in which you specify the adapter name will not be shown for the templates on your new tab.

`<xmltemplate>`

You can define one or more `<xmltemplate>` tags inside a `<group>` tag.

Each `<xmltemplate>` tag has the following mandatory attributes:

- `filename`

The name of an existing custom layout file in the *cisconfig* folder.

Tip: If you want to create a custom layout template for a Natural page (that is, a page which has the NATPAGE control as the top node), it is recommended that the name of your layout file starts with either "editorTemplateNAT" or "editor-TemplateNJX". Otherwise, if you define a different file name, the text box **Natural adapter**, in which you specify the name of the adapter that is to be generated, will not be shown for your custom layout template in the **New Ajax Page Layout** dialog box.

- `image`

The name of an image file. This image will be shown in the **New Ajax Page Layout** dialog box. If the image file is not stored in the root of the *cisconfig* folder, you have to specify a relative path with the file name.

If you want, you can copy the standard image file for Natural pages. Its name is *templat-enatural.jpg* and you can find it in your Eclipse workspace, under *.naturalone\apache-tomcat\webapps\cisnatural\HTMLBasedGUI\images*. You can copy it, for example, to your *cisconfig* folder.

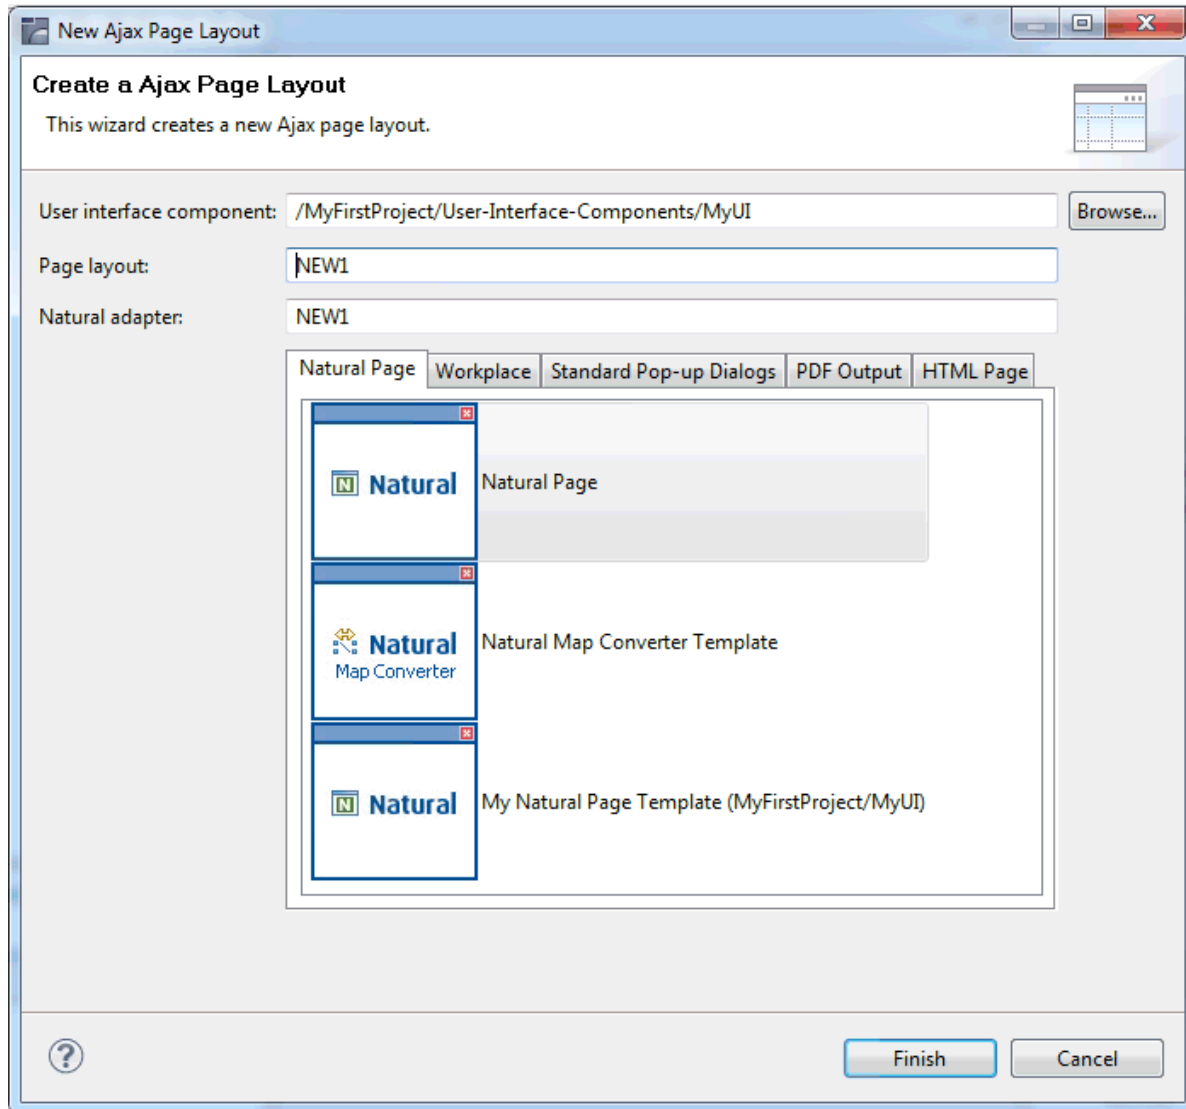

You can also add subfolders to your *cisconfig* folder. For example, you can add a *templates* folder which is to contain all of your custom layout templates, and an *images* folder which is to contain all of your images. It is important that the *editortemplates.xml* configuration file can always be found in the root of the *cisconfig* folder - you must not move this file to a subfolder.

- info

A brief text describing the custom layout template. For example, "My Natural Page Template". This info text will be shown in the **New Ajax Page Layout** dialog box, next to the image.

- 4 To check whether your custom layout template is shown in the **New Ajax Page Layout** dialog box, **create** a new layout.

The following example shows a custom layout template with the info text "My Natural Page Template". This template has been defined with the above *editortemplates.xml* file.

The information in parentheses behind the info text indicates the location of the template (project name and user interface component).

Your custom templates are always shown below the default layout templates. They are shown in the same sequence as defined in the *editortemplates.xml* file.

3

Defining the XML Layout

- Previewing the Layout 36
- Setting the Properties for a Control 39
- Changing the Appearance of Text 40
- Adding Controls to the Layout 42
- Creating a Folder for Images 43
- Defining a Background Image 44
- Defining a Style Sheet 45
- Defining Hotkeys 45
- Managing the Nodes in the Layout Area 47
- Managing the Controls in the Preview Area (SWT Only) 49
- Viewing the XML Code 50
- Viewing the Layout Painter Protocol 51
- Saving the Layout 52
- Viewing the XML to HTML Generation Log 53
- Layout Tester 53

Previewing the Layout

If you want to find out how the current layout definitions are rendered on the page, you can preview the layout. The preview of the layout is shown in the preview area. For example:

The preview area is a sensitive area. When you select a control in the preview area (for example, the title bar), this control is automatically selected in the layout tree.

Note: If you want to design your page layouts with a right-to-left (RTL) layout direction, you can set this in the Ajax Developer **preferences** (as a default for new user interface components), when **creating** a new user interface component, or when changing the **properties** of an existing user interface component.

▶ To preview the layout

- From the **Ajax Developer** menu, choose **Refresh Preview**.

Or:

Choose the following button from the Ajax Developer toolbar:

The preview area is updated according to the defined preview mode (see [below](#)).

If the system finds wrong definitions, a message is displayed in the **Problems** view. You can view the protocol to display more information about the problems that occurred when generating the preview page. See [Viewing the Layout Painter Protocol](#).

Changing the Preview Mode

There are two different preview modes:

Run Application

This is the default setting.

For page layouts other than NATPAGE layouts, the latest changes to the adapter class are used when you preview your layout.

For NATPAGE layouts, only generic Java-side classes, which are part of the Application Designer framework, are used for the preview. The Natural adapter itself is not run. To run a NATPAGE layout with the Natural adapter, you use the **NaturalONE > Execute** command with the corresponding Natural program.

Screen Test Only

For page layouts other than NATPAGE layouts: When the name of an adapter class has not been defined in the `model` property of the page, or when an adapter class has been defined which does not yet exist, an error screen is shown when you try to preview your layout. In this case, you have the possibility to activate **Screen Test Only**. Your layout will then be loaded with an empty adapter. This means that you will not have any functionality. Any changes that you make in your Java development environment will not be reflected in the preview.

For NATPAGE layouts: Instead of the generic Java-side classes of the Application Designer framework, which are executed when you choose **Run Application**, the layout is loaded with the same empty adapter as described above for non-NATPAGE layouts. For NATPAGE layouts, **Screen Test Only** is only used for troubleshooting. If **Run Application** fails, you can use **Screen Test Only**, for example, to verify whether Java Scripting and the basic Application Designer framework are able to load the page layout properly.

▶ **To change the preview mode**

- From the **Ajax Developer** menu, choose **Preview Mode** > *mode*, where *mode* is one of the preview modes described above.

Changing the Display Mode

When you change the display mode, this is immediately considered in the preview area.

By default, the layout display mode as defined in the **project properties** is used. However, by choosing a different display mode (HTML or SWT) from the **Ajax Developer** menu, you can temporarily change the preview without having to change the settings in the project properties.

The menu provides for selection the following display modes:

HTML

When this display mode is active, the preview is shown as in the browser.

SWT

When this display mode is active, the preview is shown as in the SWT client.

Project Settings

This is the default setting. When this display mode is active, the corresponding settings from the project properties are used.

▶ **To change the display mode**

- From the **Ajax Developer** menu, choose **Display Mode** > *mode*, where *mode* is one of the display modes described above.

Previewing the Layout in a New Browser Window

You can display and test the current layout, which is normally shown in the preview area, in a separate browser window. The browser shows the URL that is used to invoke this page.

▶ **To preview the layout in a new browser window**

- From the **Ajax Developer** menu, choose **Preview in New Browser Window**.

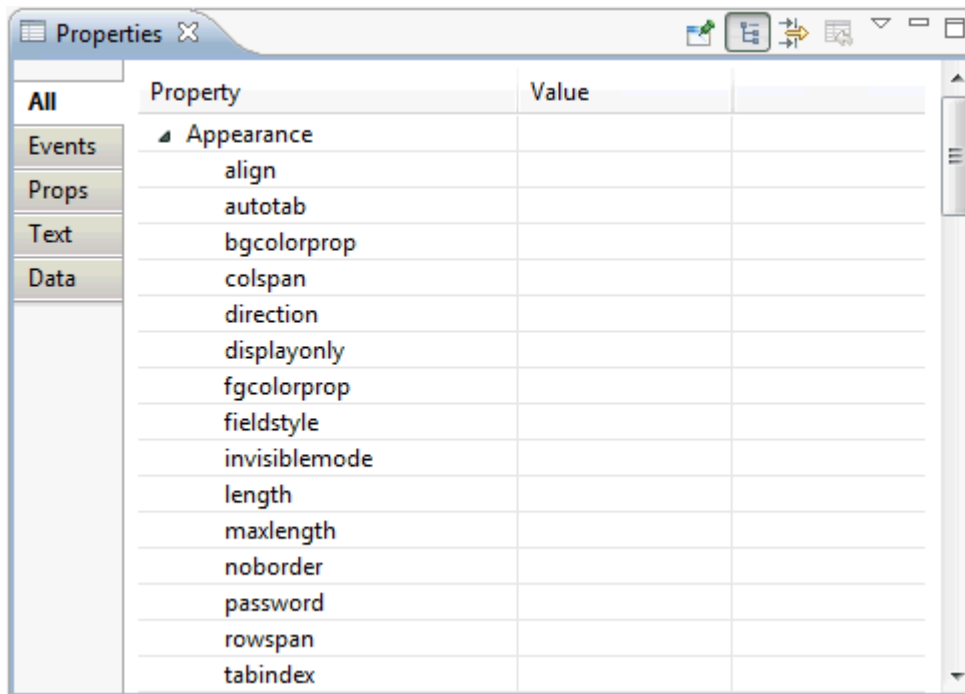

Or:

Choose the following button from the Ajax Developer toolbar:

Setting the Properties for a Control

When you select a control in the layout area or in the preview area, its properties are shown in the **Properties** view and you can edit them immediately. Example:

The **All** tab is always provided for all controls. The availability of other tabs depends on the control which is currently selected.

The **Props** tab is only shown when the control has *prop properties (such as `visibleprop`), and the **Events** tab is only shown when the control has *method properties (such as `contextmenumethod`). These tabs are provided for your convenience. They show the properties which bear a reference to the program code. However, the properties that are shown on these tabs are also shown on the **All** tab.

When it is possible to change, for example, the font for text on a control, the **Text** tab is available. For further information, see [Changing the Appearance of Text](#).

The **Data** tab is only shown for field controls. It shows any validation rules or formulae that have been defined for the field. Using the corresponding **Edit** button, you can invoke either the validation rules editor or the formula editor. For further information, see [Using the Validation Rules Editor](#) or [Using the Formula Editor](#).

▶ **To set a property using the Properties view**

- 1 Select the control in the layout area or in the preview area.

The properties for the selected control are now shown in the **Properties** view. For some properties, default values are provided.

- 2 Specify the value for the required property.

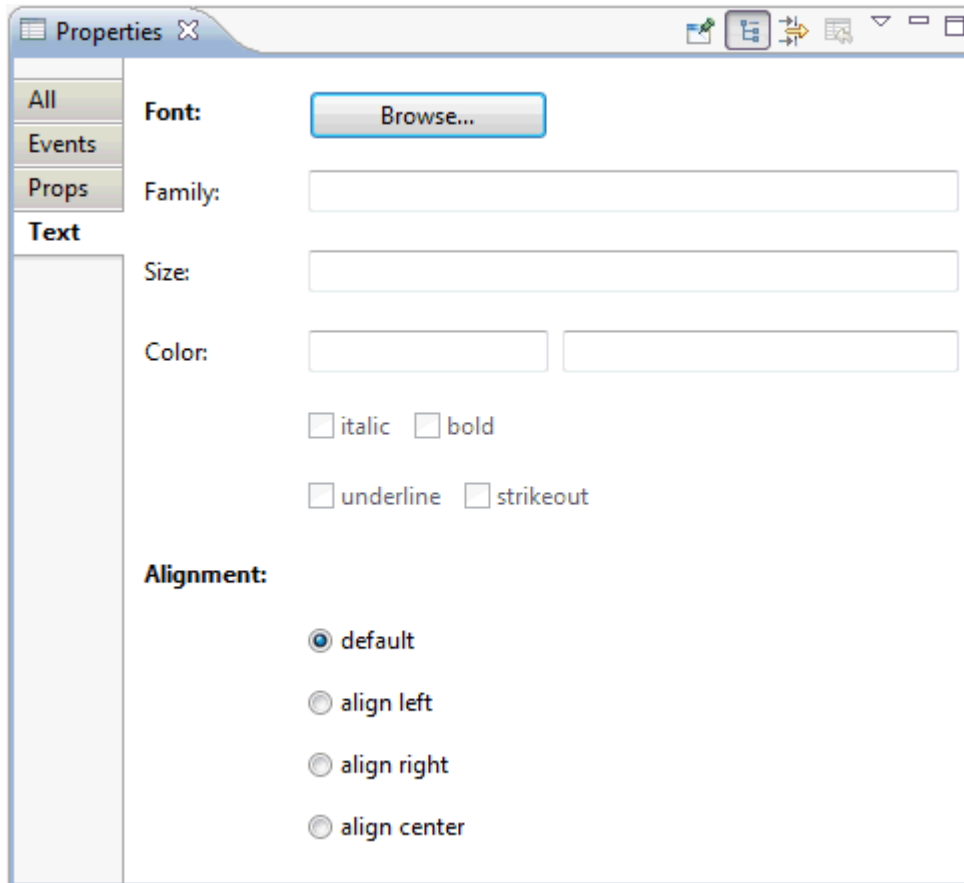

Note: The values of some important properties (for example, the `name` or `textid` of the **Title Bar** control) are shown in the layout area, in round brackets after the XML tag. If you modify the value of such a property, the changed value will be shown in the layout area.

Changing the Appearance of Text

Instead of setting the corresponding property for a control, you can change the appearance of text (for example, on a button) using the **Text** tab of the **Properties** view. This tab is available for all controls for which the appearance of text can be changed.

The **Text** tab provides for selection only those options which make sense with the selected control. Example for a button:

► **To change the appearance of text**

- 1 Select the control in the layout area or in the preview area.
- 2 Select the **Text** tab of the **Properties** view.
- 3 Choose the **Browse** button.

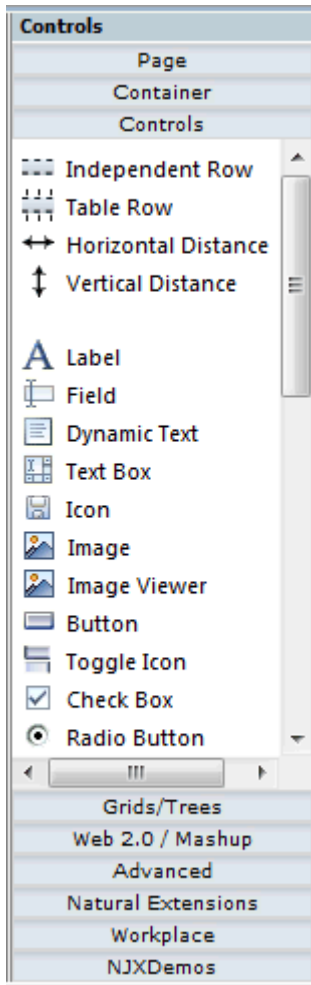

A dialog appears in which you can specify all required settings (such font family, font color or italics). These settings are then automatically entered on the **Text** tab.

- 4 If you want to change the alignment, select the corresponding option button.

Your changes are immediately shown in the preview area.

Adding Controls to the Layout

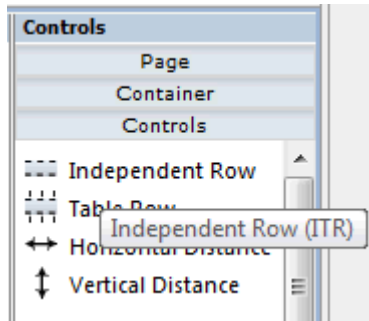

The controls that you can add to the layout can be found in the various sections of the controls palette. You simply drag them from the controls palette onto the corresponding node in the layout area or to the preview area. The preview area is immediately refreshed.

▶ To add a control to the layout

- 1 Open the required section of the controls palette by choosing the corresponding button (for example, the **Controls** button).

When you move the mouse over a control, a tool tip appears which also displays the control name which will be used in the XML layout. For example:

- 2 Drag the control from the controls palette onto the required node in the layout area.

Or:

Drag the control from the controls palette and drop it in the preview area.

Note: A control can only be inserted at a valid position. Thus, it may happen that the control is not inserted in the node which was highlighted when you dropped the control, but at a different position.

When you drop information, the system will sometimes respond by offering a context menu with certain options about where to place the control. Depending on the current context, different commands are available. For example:

The new node is automatically selected in the layout area so that you can maintain its properties directly in the **Properties** view

Creating a Folder for Images

All resources that your user interface component needs (such as images) must be contained in your project directory in the Eclipse workspace. It is good practice to create a specific folder for these resources.

▶ **To create a folder for images**

- 1 In the **Navigator** view or in the **Natural Navigator** view, select the user interface component for which you want to create a folder.
- 2 Invoke the context menu and choose **New > Other**.
- 3 In the resulting dialog box, expand the **General** node, select **Folder** and choose the **Next** button.
- 4 Specify a folder name (for example, "images") and then choose the **Finish** button.
- 5 Place all images that you want to use in the images folder that you have just created.

Defining a Background Image

You can define a background image for your page. The image must be a file with the extension *gif*, *jpeg* or *jpg*.

▶ **To define a background image**

- 1 Select a control for which a background image can be set.

Note: When a background image cannot be set for a control, the **Insert Background Image** command is disabled.

- 2 From the **Ajax Developer** menu, choose **Insert Background Image**.

Or:

Choose the following button from the Ajax Developer toolbar:

A dialog appears.

- 3 Select the image file from your images folder (see also [Creating a Folder for Images](#)).

The path to the image will automatically be converted to a relative path.

- 4 Choose the **Open** button.

The correct relative URL is automatically set in the corresponding property. In different controls, different properties are used to support background images. Background images are supported, for example, by the `pagebodystyle` property of the `PAGEBODY` control and the `titlestyle` property of the `TITLEBAR` control.

The correct style definition including the relative URL for the background image file is automatically set in the corresponding property. For example:

```
background-image:url(images/absbackground_small.gif)
```

Defining a Style Sheet

You can assign a style sheet to your page. This can either be a predefined style sheet or one of your own style sheets that you have created using the [Style Sheet Editor](#). The style sheet must be a file with the extension *css*.

Instead of setting the corresponding property for the page (see *Static Selection of the Style Sheet File in Special Development Topics*), you can define a style sheet as described below.

▶ To define a style sheet

- 1 From the **Ajax Developer** menu, choose **Insert Style Sheet**.

Or:

Choose the following button from the Ajax Developer toolbar:

A dialog appears.

- 2 Specify the path to your style sheet.

You have to specify a style sheet from your local file system. The file must be located in the same directory as your web application (or any subdirectory). When you specify an absolute path, this will automatically be converted to a relative path.

Defining Hotkeys

You can assign hotkeys to pages and to the controls `FIELD` and `ROWTABLEAREA2`. For example, you can define the hotkey `CTRL+S` for calling the method `onSave`.

See also *Extended Hot Key Management* in the *Special Development Topics*.

► **To define hotkeys**

- 1 Select the control in the layout area or in the preview area.

 **Note:** When a control is selected for which hotkeys cannot be defined, your hotkey definition will apply to the page.

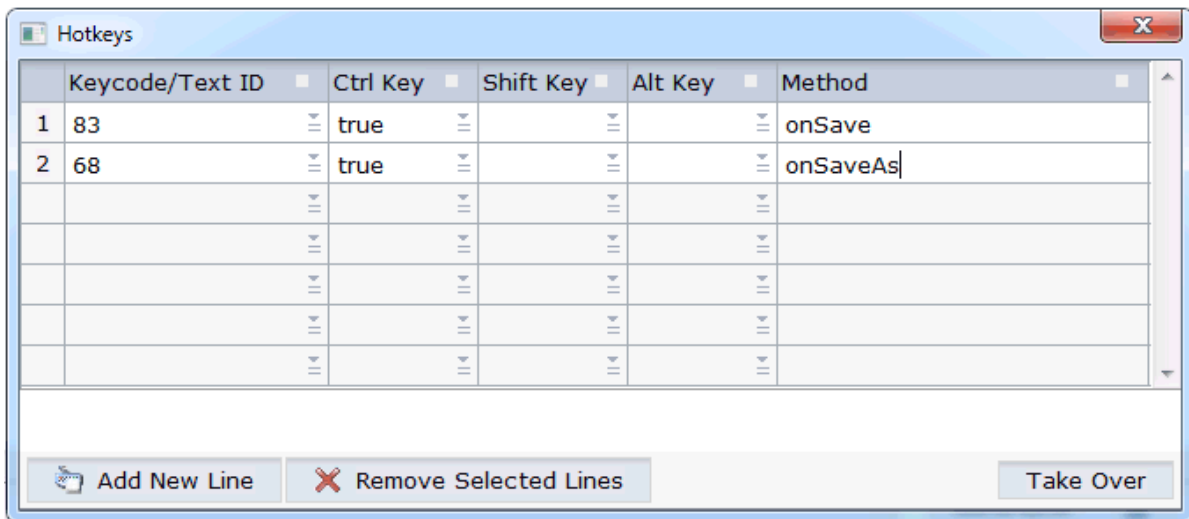

- 2 From the **Ajax Developer** menu, choose **Insert Hotkeys**.

Or:

Choose the following button from the Ajax Developer toolbar:

A dialog appears. When hotkeys have already been defined, they are shown. Example:

- 3 When hotkeys have already been defined, choose the **Add New Line** button to add an additional hotkey.

 **Note:** To remove a hotkey, select the corresponding row and choose the **Remove Selected Lines** button.

- 4 From the drop-down list box in the first column, select the key that you want to use as a hotkey. For example, "83" represents the s key and "120" represents the F9 key.

Or:

In the text box of the drop-down list box in the first column, enter a text ID that is to be translated by the multi language management.

- 5 Define each key (CTRL, SHIFT and/or ALT) which is to be used for the hotkey by selecting "true" from the corresponding drop-down list box.

Note: If neither "true" nor "false" is selected for a key, the default setting "false" is used.

- 6 In the **Method** column, specify the name of the method that is to be invoked when the user presses the hotkey.
- 7 When all hotkeys have been defined, choose the **Take Over** button.

Managing the Nodes in the Layout Area

The following topics are covered below:

- [Moving Nodes](#)
- [Using the Clipboard](#)
- [Drag-and-Drop](#)
- [Context Menus](#)

Moving Nodes

You can manage the nodes in the layout area using the following buttons which are shown below the layout tree:

Button	Description
	Moves the selected node up to first position in the tree.
	Moves the selected node up to the previous position in the tree.
	Moves the selected node down to the next position in the tree.
	Moves the selected node down to last position in the tree.

When an operation is not allowed, clicking on the corresponding button has no effect.

Using the Clipboard

You can manage the nodes in the layout tree using the following commands from the **Edit** menu of Eclipse:

Command	Description
Cut	Cuts the selected node.
Copy	Copies the selected node.
Delete	Deletes the selected node.
Undo	Undoes the previous action. The previous action can be, for example, a move operation or a changed property value.
Redo	Redoes the previous undo action.

Note: To copy and paste information in the **Properties** view, use the key combinations CTRL+C and CTRL+V.

Drag-and-Drop

In the layout area, you copy or move the nodes using drag-and-drop.

▶ To copy or move a node using drag-and-drop

- 1 In the layout area, select the node you want to move so that it is highlighted.

Press SHIFT or CTRL, if you want to select more than one node.

- 2 Press the left mouse button and keep it pressed.
- 3 Drag the mouse to the target node.

While you drag the mouse, a tool tip in light colors is shown for the node(s) you are currently dragging.

- 4 Release the mouse button.

A context menu appears and you have choose the location where you want to place the copy or the moved item (for example, in front of the target node).

Note: When the copy or move operation is not allowed, the context menu does not appear.

- 5 Choose the required command from the context menu.

Note: To cancel the drag process, move the mouse outside the context menu. The context menu will disappear and any selected nodes will keep their current position.

Context Menus

You can manage the nodes in the layout tree using context menus. The following commands may appear in a context menu:

Command	Description
Add as first Subnode	Adds a control as the first subnode of the selected node. A cascading menu is available for this command, containing all controls that can be added as a subnode of the selected node.
Add as last Subnode	Adds a control as the last subnode of the selected node. A cascading menu is available for this command, containing all controls that can be added as a subnode of the selected node.
Add as preceding Sidenode	Adds a control before the selected node, on the same level as the selected node. A cascading menu is available for this command, containing all controls that can be added as a sidenode of the selected node.
Add as subsequent Sidenode	Adds a control after the selected node, on the same level as the selected node. A cascading menu is available for this command, containing all controls that can be added as a sidenode of the selected node.
Cut	Cuts the selected node.
Copy	Copies the selected node.
Paste as first Subnode	Pastes the cut or copied node as the first subnode of the selected node.
Paste as last Subnode	Pastes the cut or copied node as the last subnode of the selected node.
Remove	Deletes the selected node.
Open all Subnodes	Opens all subnodes of the selected node.
Close all Subnodes	Closes all subnodes of the selected node.

Managing the Controls in the Preview Area (SWT Only)

When the display mode has been set to SWT, you can manage controls directly in the preview area.

When you select a control in the preview area, it is highlighted with a different color in the layout area. This indicates that you can copy, move or resize the control.

The following topics are covered below:

- [Moving and Copying Controls in the Preview Area](#)

- [Resizing Controls in the Preview Area](#)

Moving and Copying Controls in the Preview Area

You can move or copy a control or groups of controls directly in the preview area.

Note: To select more than one control, press CTRL while selecting the controls.

▶ To move controls in the preview area

- 1 Select the controls that you want to move.
- 2 Drag the controls to a new valid position.

▶ To copy controls in the preview area

- 1 Select the controls that you want to copy.
- 2 Press CTRL and drag the controls to a valid position at which it is possible to insert the copies.

Resizing Controls in the Preview Area

You can set the width and/or height of a control directly in the preview area.

▶ To resize a control in the preview area

- 1 Select the control that you want to resize.
- 2 Move the mouse pointer over the dashed border of the selected control.

The mouse pointer changes, indicating that you can start the resizing.

- 3 Press the mouse button and drag the border until the control has the desired width or height.
- 4 Release the mouse button.

Viewing the XML Code

When creating the layout, you can view the currently defined XML code at any point of time.

▶ To view the XML code

- Choose the **XML** tab which is shown at the bottom of the Layout Painter.

Information such as the following is shown:

```

1 <?xml version="1.0" encoding="UTF-8"?>
2 <natpage natkcheck="true" natsinglebyte="true" xmlns:njx="http://www.soft
3 <titlebar name="New Natural Page">
4 </titlebar>
5 <header withdistance="false">
6 <button name="Exit" method="onExit">
7 </button>
8 </header>
9 <pagebody>
10 </pagebody>
11 <statusbar withdistance="false">
12 </statusbar>
13 </natpage>
14
15
16

```

 **Note:** The properties which you leave blank in the **Properties** view are not shown in the XML code.

Viewing the Layout Painter Protocol

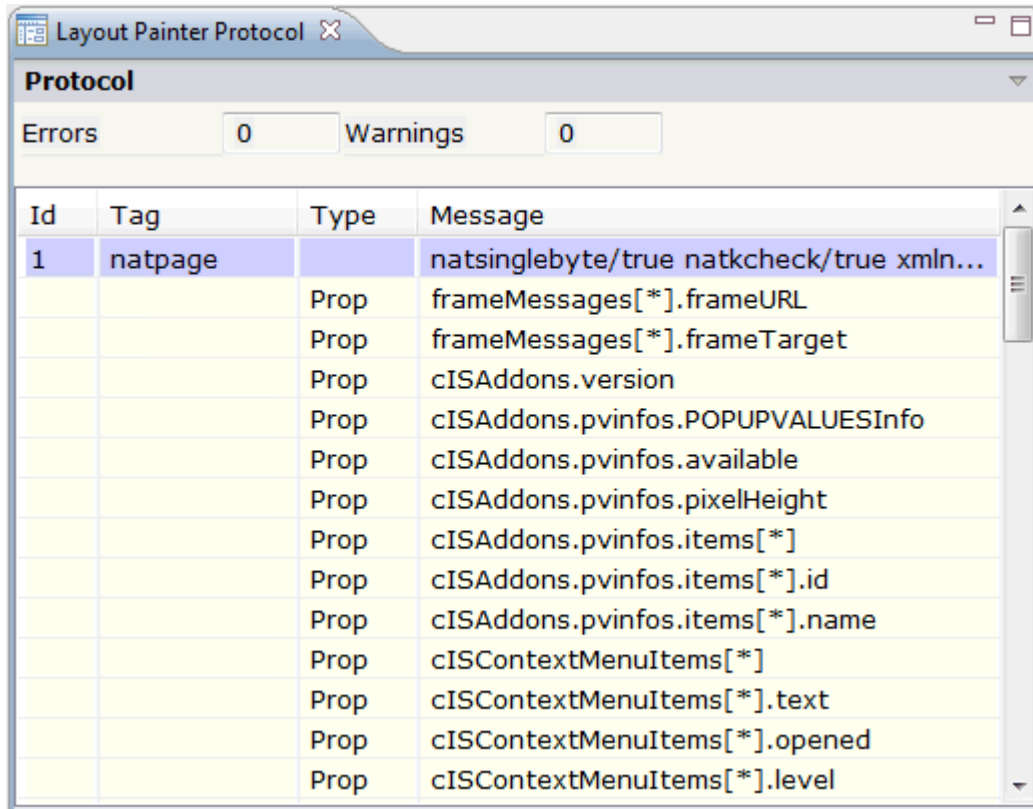

When you save the page layout or build your project, errors and warnings are shown in the **Problems** view, which is a standard Eclipse view. An error occurs, for example, when a value has not been set for a mandatory property. When you click an error or warning, the control containing the error is selected.

As an alternative to the **Problems** view, you can list the errors and warnings for the current layout in the **Layout Painter Protocol** view. The protocol lists additional information about the controls in the order in which the controls were found in the page layout.

▶ To view the protocol

- From the **Ajax Developer** menu, choose **Show Protocol**.

The protocol is shown in the **Layout Painter Protocol** view.

When you select an entry in the **Layout Painter Protocol** view, the corresponding control is automatically selected in the layout tree.

Saving the Layout

When you save the layout, all of your changes in the Layout Painter are saved.

When you save a layout for the first time, an HTML file is generated (in addition to the XML file) which is placed into the root directory of your application project. This HTML file is updated each time you save the layout.

For NATPAGE layouts, the corresponding Natural adapter is also generated.

Note: When you save the page, the **preview area** is automatically updated.

▶ To save the page

- Use the standard Eclipse functionality for saving (for example, CTRL+S).

Viewing the XML to HTML Generation Log

You can display information on the controls that have been written to the generated HTML page.

▶ **To view the log**

- From the **Ajax Developer** menu, choose **Show Log**.

A dialog appears. For example:

```

XML To HTML Generation Log
20130313/163751/833 </titlebar>
20130313/163751/833 </button>
20130313/163751/833 </header>
20130313/163751/833 </pagebody>
20130313/163751/833 </statusbar>
20130313/163751/833 </natpage>
20130313/163751/834 </titlebar>
20130313/163751/835 </button>
20130313/163751/835 </header>
20130313/163751/835 </pagebody>
20130313/163751/835 </statusbar>
20130313/163751/835 </page>
20130313/163751/836 <page> (1) model/com.softwareag.cis.adapter.MyFirstUI+NEW1
natsinglebyte/true natkcheck/true xmlns:njx/http://www.softwareag.com/njx/njxMapConverter
  
```

Layout Tester

The layout tester can be used to test the currently defined layout according to the display mode which is defined in the properties of the project: it is either shown as in the browser or as in the SWT client.

▶ **To invoke the layout tester**

- 1 Select the layout in the **Navigator** view or in the **Natural Navigator** view.
- 2 Invoke the context menu and choose **Open With > Layout Tester**.

4 Using the Code Assistant

- About the Code Assistant 56
- Code Template 56
- Opening the Code Assistant 56
- Code Introspection 57
- Generating the Code 58
- Editing the Adapter Code 59
- Saving Changes 60
- Changes from the Outside 61

About the Code Assistant

The Code Assistant only applies to PAGE layouts.

When developing page layouts in Java, automatic code modifications do not occur. For example, when you set the `valueprop` property in a FIELD control, the `set()` and `get()` methods are not automatically created in the underlying Java adapter class. Using the Code Assistant, however, you can generate code for all properties and methods which are explicitly referenced in the page layout. The compilation of the modified adapter class itself is done in your Java development environment (for example, in Eclipse).

When developing page layouts in Natural, the corresponding Natural code for the properties and methods is automatically generated when you **build a user interface component**, when you build your project in Eclipse, or when you simply **save** a modified layout in Eclipse and the **Build Automatically** command in the **Project** menu is activated. Therefore, the Code Assistant is not required for NATPAGE layouts and the corresponding menu commands are disabled.

Code Template

Before you open the Code Assistant, make sure that the `model` property of the page contains the correct adapter class. The default entry for this property is "DummyAdapter".

The Code Assistant looks in the source directory for the adapter class you have set with the `model` property. If the class cannot be found, the Code Assistant loads a code template.

The code template is stored in the directory `<your-webapplication>/cis/config`. For NaturalONE, this is usually `<webcontainerinstalldir>/webapps/cisnatural/cis/config`. Otherwise, it is usually `<webcontainerinstalldir>/webapps/cis/cis/config`.

The name of the code template is `adapterTemplate.java`. You can change this template according to your needs.

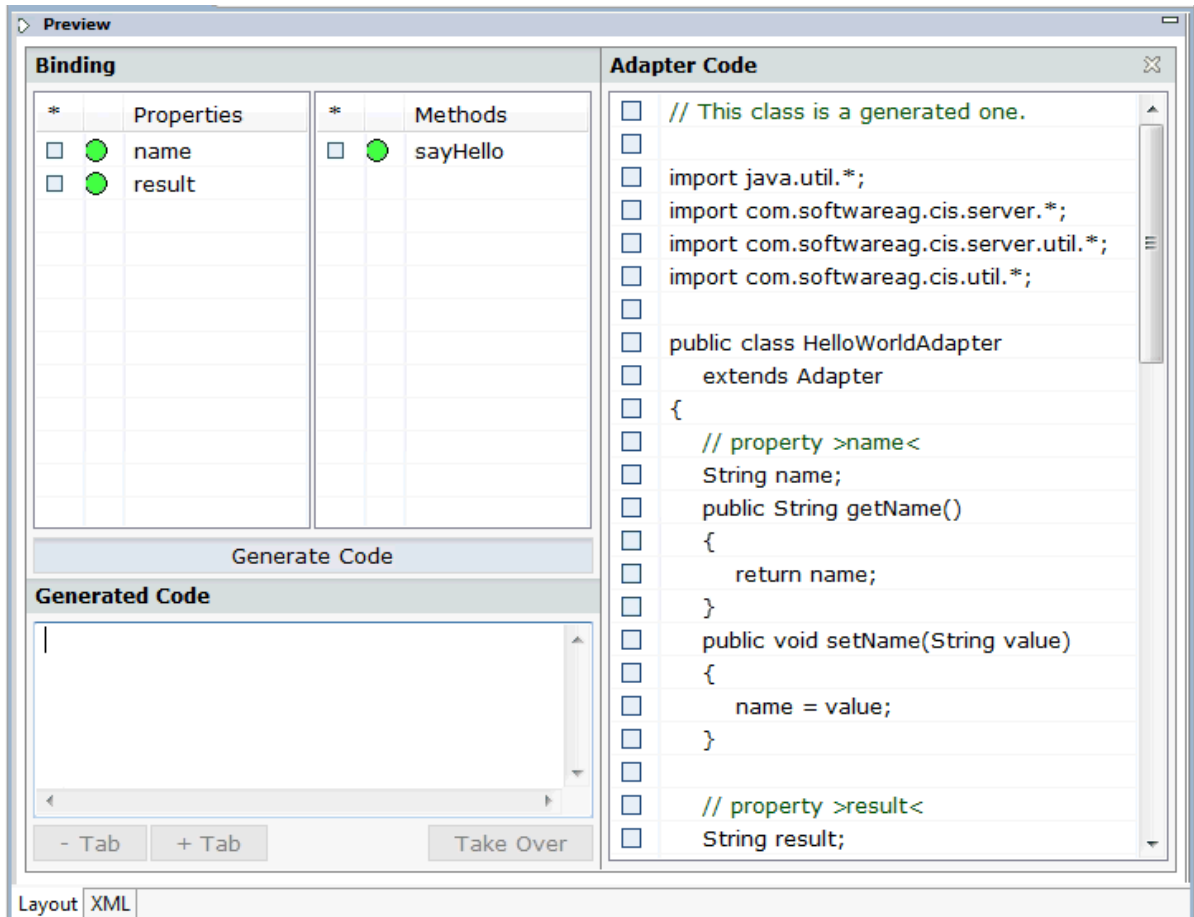

Opening the Code Assistant

In order to read and write source code, the Code Assistant needs to know where the Java sources are kept. This information is stored in the file `ciseditorconfig.xml` of each user interface component. When working with Eclipse, a `src` subdirectory is automatically created in each user interface component and applied as a Java source directory to your Eclipse project. The corresponding settings are automatically saved to the file `ciseditorconfig.xml`.

▶ **To open the Code Assistant**

- From the **Ajax Developer** menu, choose **Open Code Assistant**.

When the Java source directory can be found, the Code Assistant is shown in the preview area. For example:

Code Introspection

The binding area at the top left of the Code Assistant lists all properties and methods that are used in the XML layout. Colored dots are shown in front of each property and method. The color of the dot indicates whether the Code Assistant could find the corresponding coding within your source code.

Introspection is done by reading and interpreting the code. Comments that highlight properties or methods are not necessary.

Possible dot colors for properties:

Green	The property's <code>get</code> and <code>set</code> methods are available.
Yellow	The <code>set</code> method is required but could not be located. The <code>get</code> method is fine.
Red	The <code>get</code> method could not be found.

Possible dot colors for methods:

Green	The method is available.
Red	The method could not be found.

When you select a property or method in the binding area, the properties are shown in the **Properties** view.

In addition, when code has already been generated for the selected property or method (see below), the corresponding line is automatically selected in the adapter code which is shown at the right of the Code Assistant.

Generating the Code

The properties and methods which cannot be found in the adapter code are indicated by red dots.

When you generate code, a framework for the property or method is generated in the adapter code.

▶ To generate code

- 1 Select the property or method for which you want to generate code.

You can also use the `SHIFT` or `CTRL` key to select multiple entries.

- 2 Choose the **Generate Code** button.

The generated code appears in the area below this button.

Check whether you really want to insert these statements into your source code. You can modify or delete the code. Any code that you manually enter here will be taken over.

- 3 Optional. Choose the **+Tab** or **-Tab** button to add or remove a tab at the beginning of the code. This applies to all code which is currently shown in the **Generated Code** area.
- 4 In the **Adapter Code** area on the right, select the line below which you want to insert the code.
- 5 Choose the **Take Over** button to insert the code below the selected line.

The color of the dot changes from red to green. This indicates that the corresponding methods are now available in the adapter code.

- 6 Save your changes.

Note: It is recommended that you save your changes each time you switch from the Code Assistant to another tool which may be shown in the preview area, and vice versa.

Editing the Adapter Code

You can edit the adapter code in different ways:

- [Editing the Adapter Code in the Java Editor](#)
- [Editing the Adapter Code Directly in the Code Assistant](#)

Editing the Adapter Code in the Java Editor

If you want to apply complex changes to the adapter code, it is recommended that you do this in the Java editor.

Important: Be sure to close the Code Assistant before you open the adapter code in the Java editor.

▶ To invoke the Java editor

- 1 In the **Navigator** view, select the page layout (that is, the XML file) for which you want to change the adapter code.
- 2 Invoke the context menu and choose **Ajax Developer > Open Java Adapter**.

Or:

When the Layout Painter is still active, open the **Ajax Developer** menu and choose **Open Java Adapter**.

Editing the Adapter Code Directly in the Code Assistant

Instead of invoking the Java editor, you can also apply smaller changes to the adapter code directly in the Code Assistant, while generating the code for the properties and methods.

▶ To edit the adapter code in the Code Assistant

- 1 Select one or more lines in the **Adapter Code** area.

To select more than one line, use CTRL or SHIFT.

- 2 Invoke the context menu and choose one of the following commands:

Command	Description
-Tab	Removes a tab from the beginning of the selected line(s).
+Tab	Adds a tab to the beginning of the selected line(s).
Cut	Cuts the selected line(s).
Copy	Copies the selected line(s).
Paste	Only available after a cut or copy operation. Pastes the cut or copied line(s) below the currently selected line.
Remove	Removes the selected line(s).

Saving Changes

You save the adapter code using the standard Eclipse functionality for saving.

Notes:

1. When editing the adapter code using the Code Assistant, it is recommended that you first close the Code Assistant before you close the Layout Painter.
2. After saving your changes to the adapter code, choose the **Refresh Preview** command so that you can see the changes in the preview area.

Changes from the Outside

Each time you **preview** the layout, the Code Assistant checks whether the file has changed on the file system. Therefore, the file attribute "last modified" is examined (not the file content). If the Code Assistant notices a file change, it checks whether it is holding own unsaved changes. If not, the class code is reloaded from the file system. If you have done changes in parallel (within your Java development environment and the Code Assistant) a dialog appears. Choose either to reload the file from disk (and lose the changes you have done within the Code Assistant) or to keep the Code Assistant changes (and lose the outside changes on the next save).

Note: You have to take care that the following case never occurs: the file has changed on file system and the Code Assistant has its own unsaved changes. Of course, it is reasonable to open the class both in your Java development environment and in the Code Assistant. It is recommended that you save or discard changes before you switch from the Code Assistant to your Java development environment (or vice versa). Otherwise, you will lose one of your changes.

5 Using the Literal Assistant

- About the Literal Assistant 64
- Opening the Literal Assistant 64
- Maintaining Literals 65
- Selecting Another Language 66
- Displaying a Comparison Language 66

About the Literal Assistant

The Literal Assistant can be used to maintain texts of different languages for the literals that are referenced within the XML layout.

The concept of the multi language management is described in *Multi Language Management*. It is recommended that you read this information before you proceed with the information below.

Note: Text can also be translated using the [Literal Translator](#).

Opening the Literal Assistant

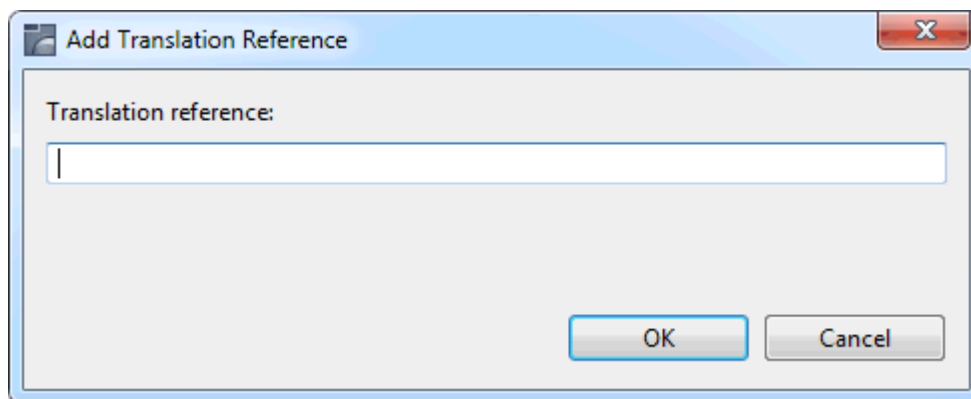

The Literal Assistant needs to know in which file the language-specific texts are kept. The name of this translation file is stored in the `translationreference` property of the page.

See also *Writing Multi Language Layouts in Multi Language Management*.

▶ To open the Literal Assistant

- 1 From the **Ajax Developer** menu, choose **Literal Assistant**.

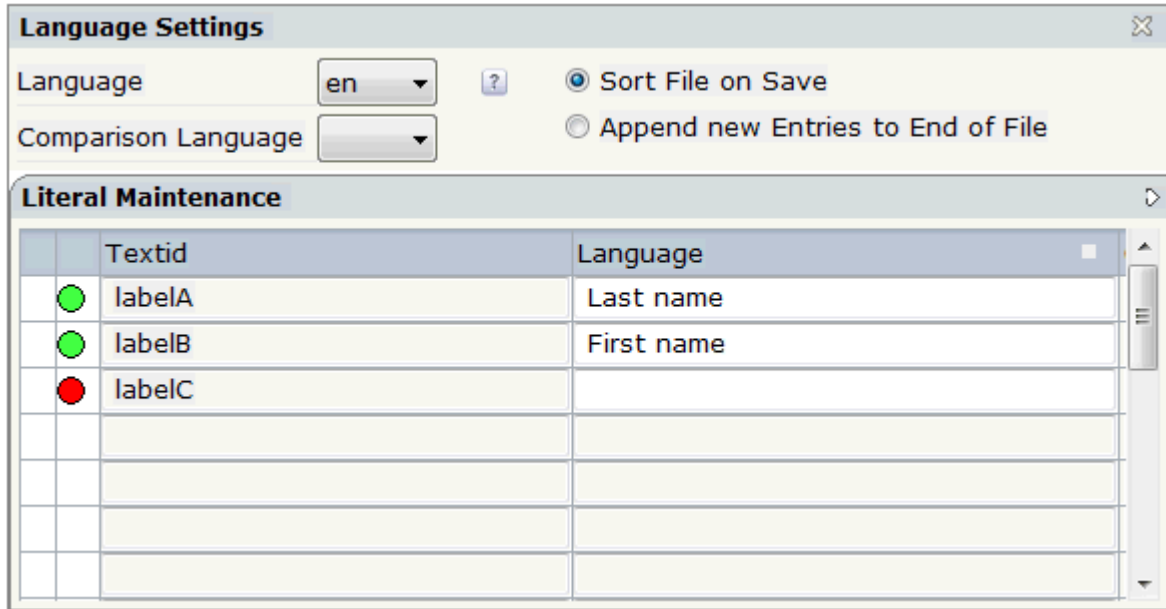

When a translation file has not yet been specified, the following dialog box appears:

- 2 Specify the name of the translation file and choose the **OK** button.

The name you specify is entered in the `translationreference` property.

The Literal Assistant appears in the editor area.

 **Note:** For multi language support, you use the `textid` property for a label (instead of the `name` property).

Maintaining Literals

All referenced literals of the currently selected language are provided in the **Literal Maintenance** area.

Colored dots are shown in front of each literal. The color of the dot indicates whether the Literal Assistant could find the corresponding text in the translation file for the currently selected language.

Possible dot colors:

Green	A text is available in the translation file.
Yellow	The translation file contains a line for the literal - but the text is empty.
Red	The literal (and text) does not yet exist in the translation file.

When you select the first column (that is, the column to the left of the colored dot), the corresponding node is automatically selected in the layout tree and the properties for this node are shown in the **Properties** view.

► To add/modify text for the current language

- 1 Enter all required text in the **Language** column.

2 Define the sequence of the entries in the translation file by selecting one of the following option buttons:

- **Sort File on Save** (ascending order)
- **Append new Entries to End of File**

3 Choose the standard Eclipse **Save** command to save your text input.

Your changes will also be available in the preview of the HTML page.

Selecting Another Language

The valid languages are determined by the existing subdirectories in the *multilanguage* directory which belongs to your user interface component. An entry for each subdirectory is provided in the **Language** drop-down list box.

Note: You may have to choose the **Refresh Preview** command to refresh the Literal Assistant so that any subdirectories you have just defined in your file system are shown in the drop-down list box.

▶ To select another language

- From the **Language** drop-down list box, select the required language.

When you have not yet saved your previous changes, a dialog appears asking whether you want to save your changes.

Important: The Literal Assistant keeps changes for one language only. If you want to maintain texts for several languages, save the changes before you switch to another language. Otherwise, you will lose input.

The selected language is shown in the **Language** column of the table.

Displaying a Comparison Language

For comparison purposes, you can display the texts of another translation file in the **Comparison Language** column. The **Comparison Language** drop-down list box contains an entry for each subdirectory in the *multilanguage* directory which belongs to your user interface component.

▶ **To display another language for comparison**

- From the **Comparison Language** drop-down list box, select the required language.

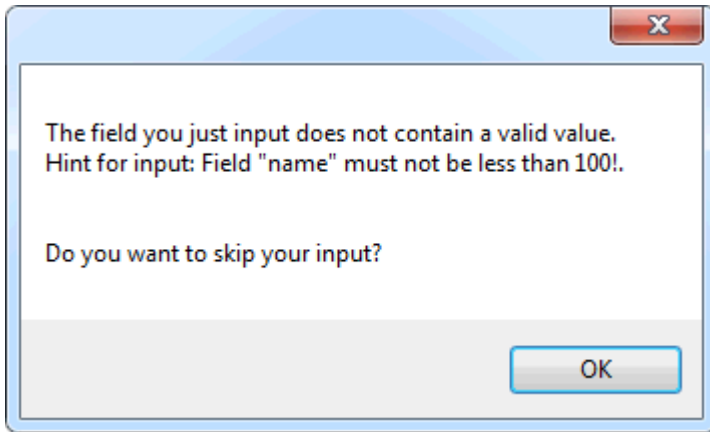

The selected language is shown in the **Comparison Language** column of the table.

6 Using the Validation Rules Editor

- About the Validation Rules Editor 70
- Opening the Validation Rules Editor 70
- Adding a New Validation Rule 71
- Displaying an Overview of All Defined Validation Rules 73

About the Validation Rules Editor

The validation rules editor can be used to define that the value that is entered in a field must meet certain conditions. You can test your validation rule in the preview area. If an invalid value is entered, a corresponding message appears. Example:

 **Important:** The validation is done on the client side.

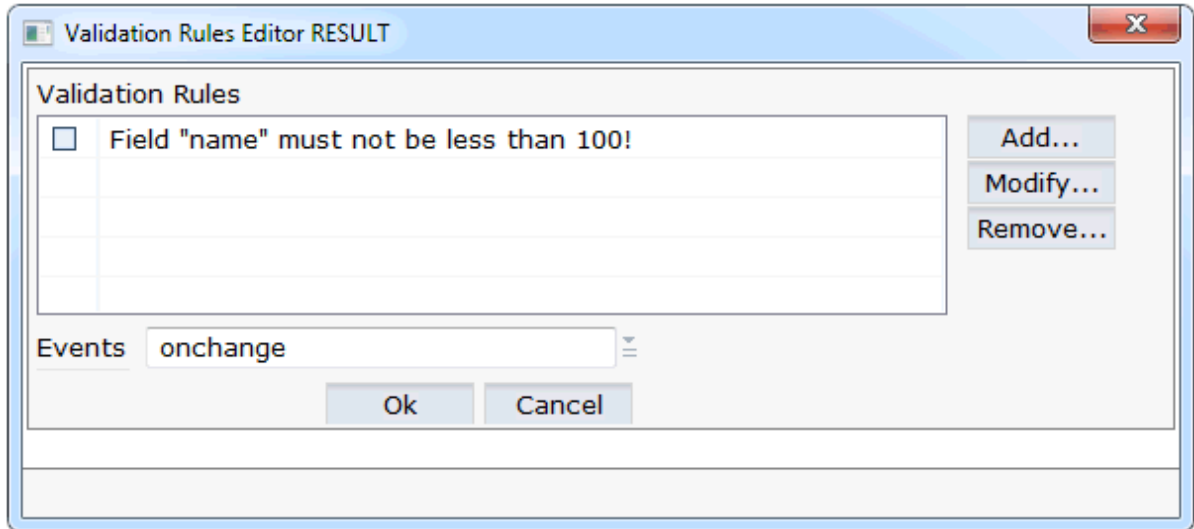

Opening the Validation Rules Editor

When you open the validation rules editor, you can add, modify and remove validation rules.

▶ To open the validation rules editor

- 1 In the layout area or preview area, select the field control that you want to validate.
- 2 From the **Ajax Developer** menu, choose **Insert/Edit Validation Rules**.

A dialog appears. If validation rules have already been defined, the messages that have been defined for these rules are shown in the text box. Example:

The following command buttons are provided:

Command Button	Description
Add	Adds a new validation rule. See below.
Modify	Modifies the selected validation rule.
Remove	Removes the selected validation rule.

Adding a New Validation Rule

The prerequisite for adding a validation rule for a field is that an adapter class or Natural adapter with the corresponding code exists for the field. Otherwise, the field does not appear in the validation rules editor.

You can add more than one validation rule.

▶ To add a new validation rule

- 1 To add a validation rule, choose the **Add** button.

Additional information is now shown at the bottom of the dialog.

The screenshot shows the 'Validation Rules Editor RESULT' dialog box. It has a title bar with a close button. The main area is divided into several sections:

- Validation Rules:** A table with columns for field name, condition, value, and operator. To the right are buttons for 'Add...', 'Modify...', and 'Remove...'.
- Events:** A dropdown menu currently showing 'onchange'. Below it are 'Ok' and 'Cancel' buttons.
- If this condition is true:(Enter date in YYYYMMDD format):** A table with columns for field name, condition, value, and operator. To the right are 'Add' and 'Delete' buttons.
- then show this error alert:** A section with a 'Message' text box and a 'Text ID' text box. Below them are 'Ok' and 'Cancel' buttons.

- 2 From the first drop-down list box, select the name of the field for which you want to add a condition.
- 3 From the second drop-down list box, select the condition (for example, "less than").
- 4 In the third box, enter the value for the condition (for example, "100").
- 5 Optional. From the fourth drop-down list box, select the operator **And** or **Or** if you want to define an additional condition. In this case, you have to choose the **Add** button which is shown in the lower part of the dialog and specify the required values in the resulting line (as described above).
- 6 In the **Message** text box, enter the message that is to appear in a dialog box when an invalid value is entered (for example: "The value in the field must not be less than 100!").

Or:

If you are working with several languages, enter a text ID in the **Text ID** text box. See also *Multi Language Management*.

- 7 From the **Events** drop-down list box, select one of the following values. This defines the behavior in the case of an error.

Event	Description
onchange	Your message will appear when the user leaves the input field.
onsubmit	Your message will appear when the information is about to be transferred to the server (for example, by choosing a Save button).

The lower part of the dialog may now look as follows:

If this condition is true:(Enter date in YYYYMMDD format)

1	name	less than	100

then show this error alert:

Message

Text ID

Ok Cancel

- 8 Optional. If you want to delete a condition, select the corresponding row and choose the **Delete** button.
- 9 To confirm the new validation rule, choose the **OK** button in the lower part of the window.

The dialog is not closed and you can add further validation rules.

- 10 To confirm all validation rules and to close the window, choose the **OK** button in the upper part of the window.

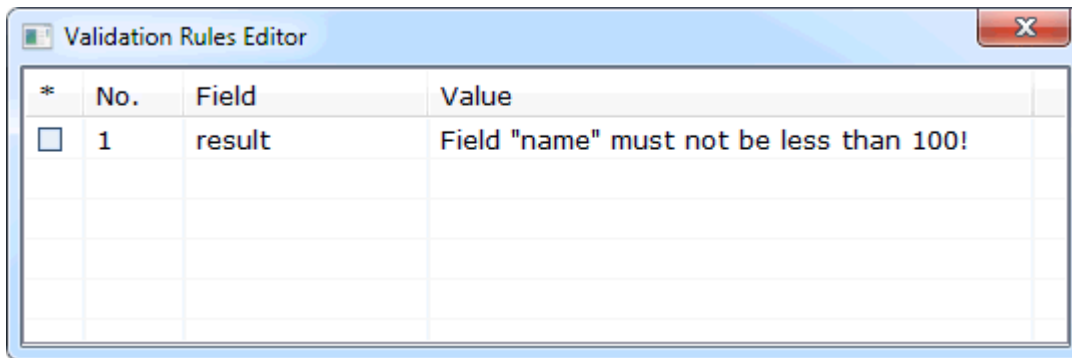

Displaying an Overview of All Defined Validation Rules

You can display a list of all validation rules which are defined in the current layout.

▶ To display an overview

- From the **Ajax Developer** menu, choose **Validation Rules Overview**.

A dialog appears. When validation rules have been defined in the current layout, they are listed in this dialog.

When you click on a validation rule, the validation rules editor appears and you can change the validation rule as described above.

7 Using the Formula Editor

- About the Formula Editor 76
- Opening the Formula Editor 76
- Adding a New Formula 77
- Displaying an Overview of All Defined Formulae 79

About the Formula Editor

The formula editor can be used, for example, to define that the sum of the fields A and B is to be shown in field C. In this case, the formula has to added to field C.

 **Important:** The formula is processed on the client side.

Opening the Formula Editor

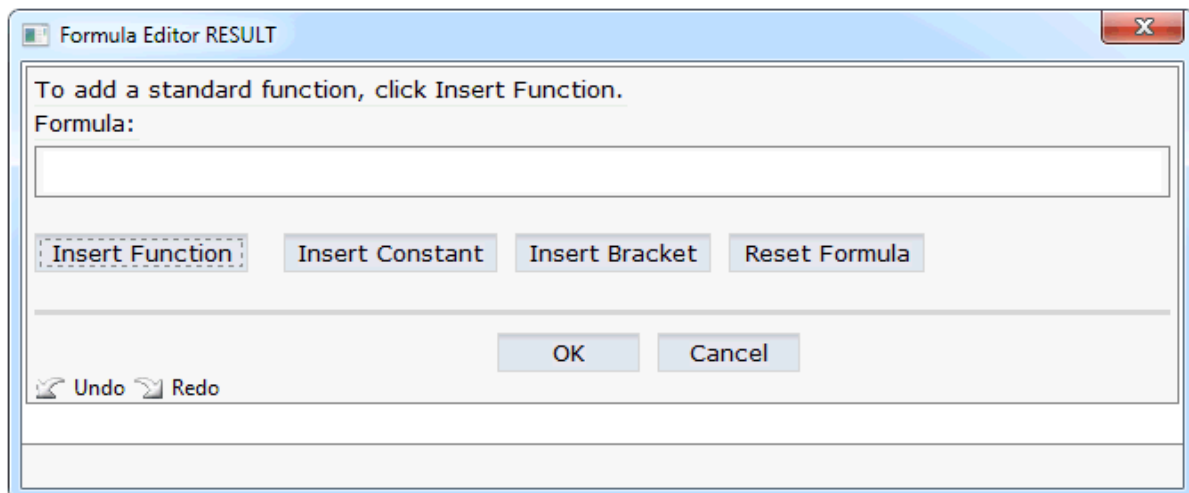

When you open the formula editor, you can add or remove a formula.

The prerequisite for adding a formula for a field is that an adapter class or Natural adapter with the corresponding code exists. The formula editor only works with fields that have valid declared properties on the adapter side.

▶ To open the formula editor

- 1 In the layout area or preview area, select the field control for which you want to add a formula.
- 2 From the **Ajax Developer** menu, choose **Insert/Edit Formula**.

A dialog appears. If a formula has already been defined for the selected field, it is shown in the dialog.

 **Important:** A function is always defined from the left to the right. It is not possible to go back in the function, for example, in order to insert a missing operator. Therefore,

you should already have a plan of your function in mind before you compose the function using the controls in the formular editor.

The following command buttons are provided:

Command Button	Description
Insert Function	Allows you to select a function (such as sum) from a drop-down list box. After you have selected a function, you define the required fields using an "insert field" link. A simple example is provided below; see Adding a New Formula .
Insert Operator	This button is only shown when applicable, that is, if at least one expression has been entered. Allows you to select an operator (such as the plus sign) from a drop-down list box.
Insert Constant	Allows you to define a constant (for example, the number "77") in a text box.
Insert Bracket	Allows you to select brackets from a drop-down list box.
Reset Formula	Deletes the formula.

Adding a New Formula

This section explains how to define a simple formula: the sum of the fields **Value A** and **Value B** is to be shown in the **Sum** field.

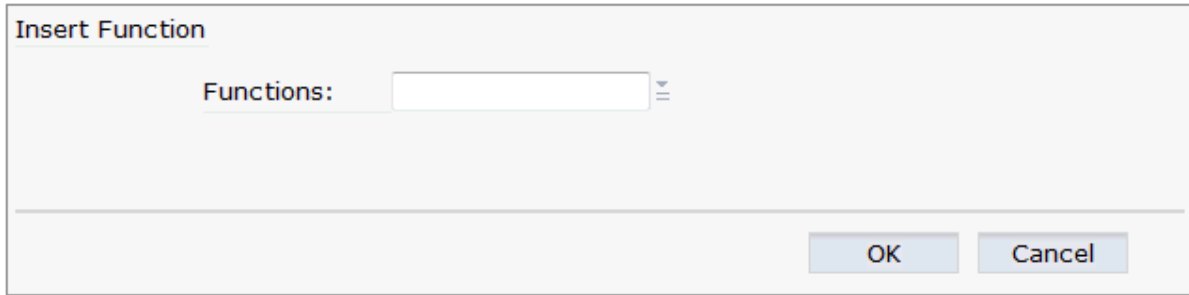

The screenshot shows a dialog box titled "Simple Sum Example" with a close button (X) in the top right corner. Inside the dialog, there are three input fields arranged vertically. The first field is labeled "Value A", the second is labeled "Value B", and the third is labeled "Sum". Each label is positioned to the left of its corresponding input box.

▶ To add a simple formula

It is assumed that the formula editor has been invoked as described [above](#) (the field was selected in which the sum is to be shown).

- 1 Choose the **Insert Function** button.

The following information is now shown at the bottom of the dialog.

- 2 Select the required function (for this example, select **sum**) from the **Functions** drop-down list box and choose the **OK** button.

The information at the bottom of the dialog is no longer shown. The selected function is now shown in the **Formula** text box, together with the link "insert field".

Note: It is not possible to edit the formula in the **Formula** text box.

- 3 Choose the "insert field" link in the **Formula** text box.

The fields that are currently defined in the layout are now shown at the bottom of the dialog. Example:

- 4 Choose a field (for this example, choose **valueA**).

The selected field is now shown in the **Formula** text box. The link "insert field" is still shown in case you want to insert more fields.

- 5 Insert all required fields as described above (for this example, choose **valueB**).

For this example, the formula should look as follows:

```
sum(valueA,valueB)
```

- 6 When the formula is complete, choose the **Cancel** button.
- 7 To close the formula editor, choose the **OK** button.

You can now test the formula in the preview area.

Displaying an Overview of All Defined Formulae

You can display a list of all formulae which are defined in the current layout.

▶ To display an overview

- From the **Ajax Developer** menu, choose **Formula Overview**.

A dialog appears. When formulae have been defined in the current layout, they are listed in this dialog.

*	No.	Field	Value
<input type="checkbox"/>	1	sum	sum(valueA,valueB)

When you click on a formula, the formula editor appears and you can change the formula as described above.

III

▪ 8 Language Manager	83
▪ 9 Literal Translator	89
▪ 10 Style Sheet Editor	95

8 Language Manager

- About the Language Manager 84
- Invoking the Language Manager 84
- Defining a New Language 85
- Opening an Existing Language 87

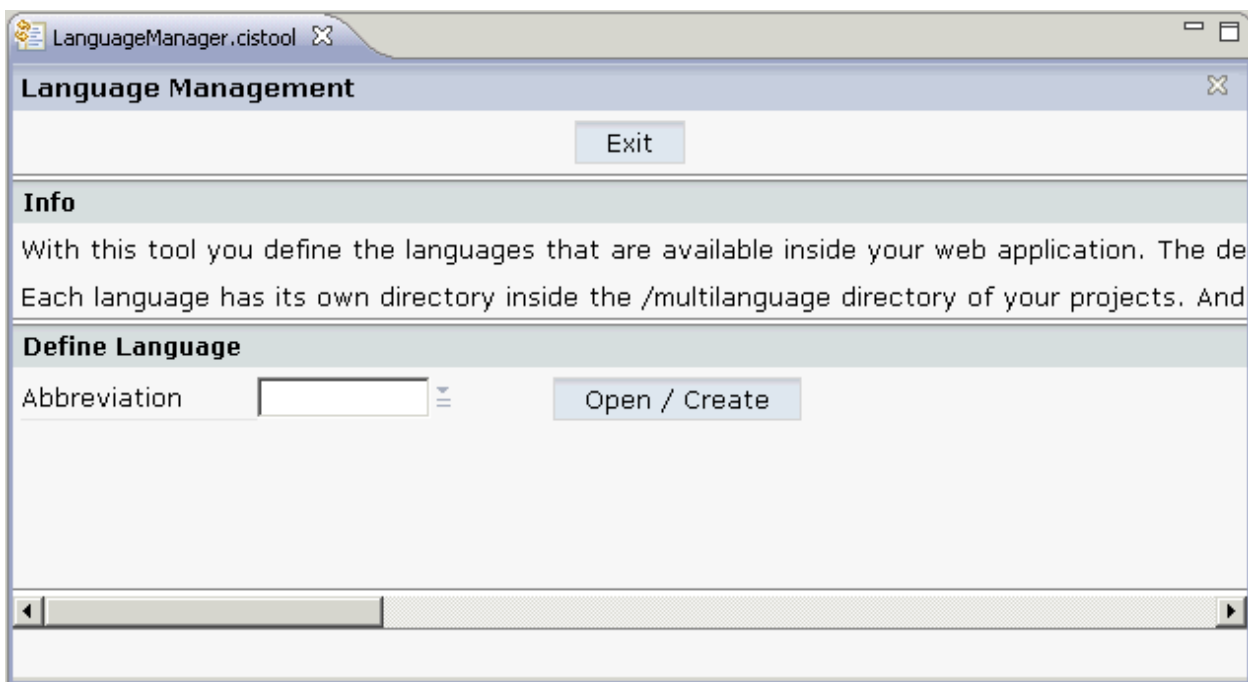

About the Language Manager

Two languages are supported by default: "en" for English and "de" for German. The Language Manager can be used to define additional languages.

The concept of the multi language management is described in *Multi Language Management*. It is recommended that you read this information before you proceed with the information below.

Invoking the Language Manager

When you invoke the Language Manager, the following dialog appears.

▶ To invoke the Language Manager

- 1 In the **Navigator** view, select the project for which you want to invoke the Language Manager.
- 2 Invoke the context menu and from the **Ajax Developer** menu, choose **Language Manager**.

Defining a New Language

When you define a new language, the required directories and certain files holding textual information will automatically be created in all existing projects.

► To define a new language

- 1 In the text box of the **Abbreviation** drop-down list box, enter the abbreviation for your new language.
- 2 Choose the **Open / Create** button.

The following information is shown.

Translate the literals and message texts listed below and press "Save" afterwards.

Literals	Messages
Date Input	<input type="text"/>
Time Input	<input type="text"/>
Text Input	<input type="text"/>
Number Input	<input type="text"/>
OK	<input type="text"/>
January	<input type="text"/>
February	<input type="text"/>
March	<input type="text"/>
April	<input type="text"/>
May	<input type="text"/>
June	<input type="text"/>
July	<input type="text"/>
August	<input type="text"/>
September	<input type="text"/>
October	<input type="text"/>
November	<input type="text"/>
December	<input type="text"/>
Today	<input type="text"/>
Hour	<input type="text"/>
Minute	<input type="text"/>
Second	<input type="text"/>
File Upload	<input type="text"/>
Upload	<input type="text"/>
Mo	<input type="text"/>
Tu	<input type="text"/>
We	<input type="text"/>
Th	<input type="text"/>
Fri	<input type="text"/>
Sa	<input type="text"/>
Su	<input type="text"/>
Ctrl	<input type="text"/>
Alt	<input type="text"/>
Shift	<input type="text"/>
No match for	<input type="text"/>

- 3 Translate all literals that are shown on the **Literals** tab.

- 4 Choose the **Messages** tab.

- 5 Translate all strings that are shown on the **Messages** tab.

Each "\n" in a string stands for a line break.

"REPLACE" is a placeholder for a variable. It must not be deleted. During runtime, the corresponding value will be used. Example:

Language 1: \nHint for input: REPLACE.\n\n\n

Language 2: \nHinweis für die Eingabe: REPLACE.\n\n\n

- 6 Choose the **Save Language** button at the bottom of the dialog.

The directories and files for the specified language abbreviation are created. A message appears in the status bar of the Language Manager.

If you want to find out which directories and files were created, click the message in the status bar.

Opening an Existing Language

You can modify the text for literals and messages that you have specified when you have defined a new language (see above).

▶ To open an existing language

- 1 In the text box of the **Abbreviation** drop-down list box, enter the abbreviation of an existing language.
- 2 Choose the **Open / Create** button.

A dialog appears showing the currently defined texts for the literals and messages.

- 3 Edit the required texts on the **Literals** and/or **Messages** tab.
- 4 Choose the **Save Language** button at the bottom of the dialog.

The texts are written to the files which have been created for the specified language abbreviation. A message appears in the status bar of the Language Manager.

If you want to find out which files were affected, click the message in the status bar to display a dialog.

9 Literal Translator

▪ About the Literal Translator	90
▪ Invoking the Literal Translator	90
▪ Loading the Literals of a Layout	91
▪ Editing the Literals	93
▪ Adding a New Text ID	93
▪ Removing Text IDs	94

About the Literal Translator

The Literal Translator can be used to translate text IDs. You can also use it to add and remove text IDs.

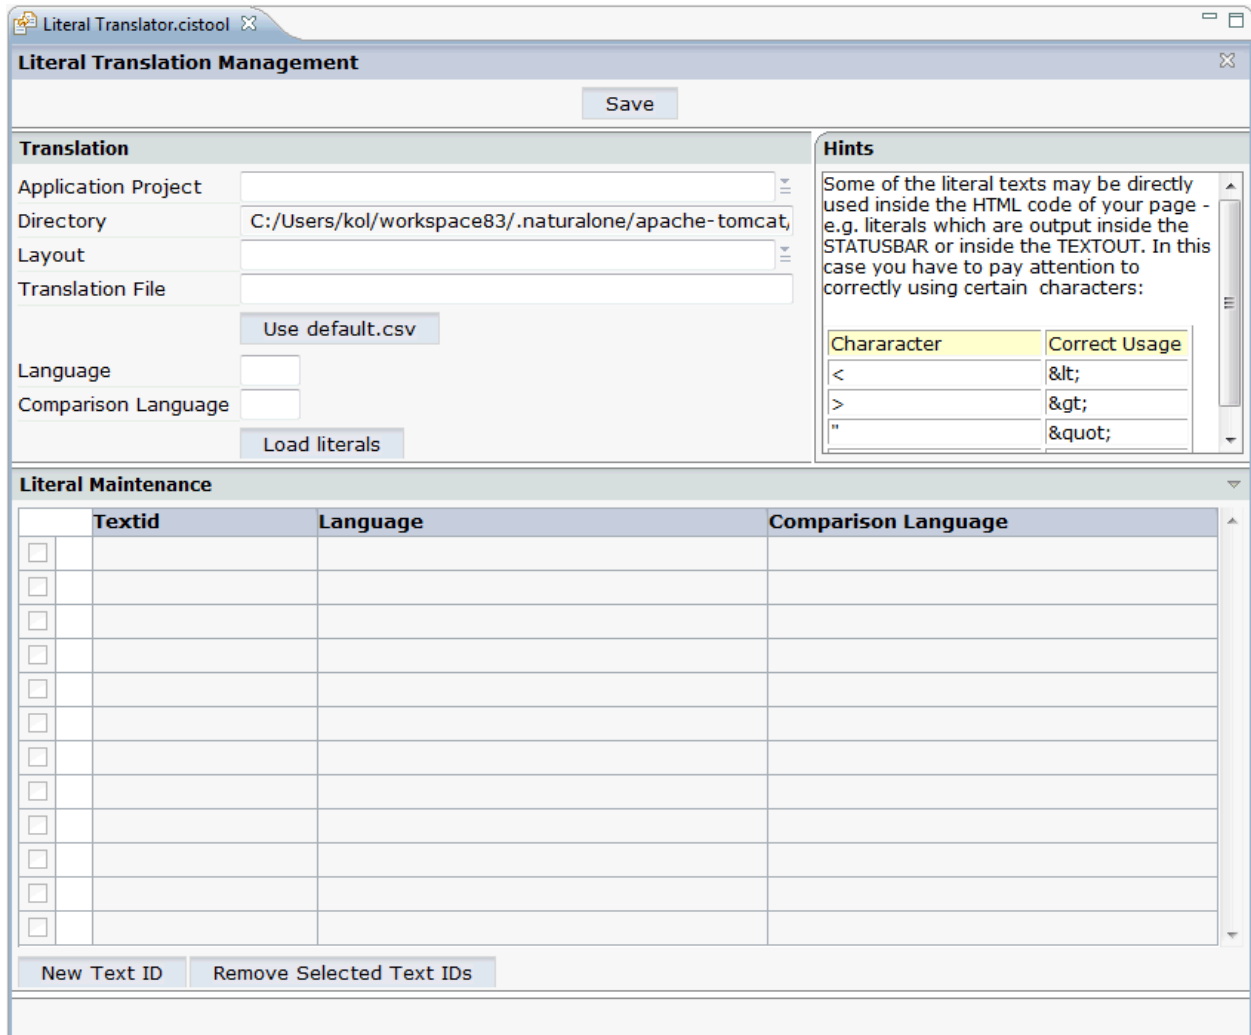

Note: Text IDs can also be translated using the [Literal Assistant](#).

The concept of the multi language management is described in *Multi Language Management*. It is recommended that you read this information before you proceed with the information below.

Invoking the Literal Translator

When you invoke the Literal Translator, the following is shown:

▶ To invoke the Literal Translator

- 1 In the **Navigator** view, select the project for which you want to invoke the Literal Translator.
- 2 Invoke the context menu and from the **Ajax Developer** menu, choose **Literal Translator**.

Loading the Literals of a Layout

You can load and modify the texts for a specific layout in one language. Optionally, can also load the literals of a second language for comparison purposes.

Note: If you want to open the literals for a different layout or project, you have to close the Literal Translator and start it once more. Otherwise, the required options are not enabled.

► **To load the literals of a layout**

- 1 In the text box of the **Application Project** drop-down list box, enter the name of the project which contains your layout.

Or:

Open the drop-down list box and choose the project from the resulting dialog.

- 2 In the text box of the **Layout** drop-down list box, enter the name of the layout for which you want to translate the literals.

Or:

Open the drop-down list box and choose the layout from the resulting dialog.

- 3 In the **Translation File** text box, enter the name and extension of your translation file.

Notes:

1. It is not required that the specified translation file already exists. You can **add** new text IDs as described below. When you choose the **Save** button, the translation file will be created and all of your definitions are written to it. Literals that have been created in this way, still have to be assigned to the corresponding controls, for example, using the **Literal Assistant**.
2. If you do not enter the name of a translation file, *default.csv* is automatically provided in this text box.
3. You can use the **Use default.csv** button to enter *default.csv* in this text box.
- 4 In the **Language** text box, enter the abbreviation for the language that you want to use. See also **Language Manager**.
- 5 Optional. If you want to display the literal of a second language for comparison purposes, enter the abbreviation for this language in the **Comparison Language** text box.
- 6 Choose the **Load literals** button.

The contents of the translation file(s) are loaded and the literals are shown at the bottom. Example:

Literal Maintenance			
	Textid	Language	Comparison Language
<input type="checkbox"/>	 inarea	Input Area	Eingabebereich
<input type="checkbox"/>	 input	Input your name and press the 'S	Geben Sie Ihren Namen ein und w
<input type="checkbox"/>	 outarea	Output Area	Ausgabebereich
<input type="checkbox"/>	 result	Result	Ergebnis
<input type="checkbox"/>			

 Literals have already been loaded

Editing the Literals

You can edit the literals that are shown in the **Language** column. It is not possible to edit the literals of the comparison language.

▶ To edit the literals

- 1 Enter the new text directly in the **Language** column.

Or:

To edit a literal in a separate dialog, choose the following icon which is shown next to the literal (this is helpful with long literals):

If you have opened a separate dialog, you have to choose the **Take Over** button in order to confirm your changes and to close the dialog.

- 2 Choose the **Save** button to write your changes to the translation file.

Adding a New Text ID

You can add a new text ID to the translation file and specify a literal for it.

▶ To add a new text ID

- 1 Choose the **New Text ID** button which is shown below the list of literals.

An empty line is added to the list.

- 2 Enter the literal in the **Language** column.
- 3 Choose the **Save** button to write the new text ID and literal to the translation file.

Removing Text IDs

You can remove one or more text IDs from the translation file.

▶ To remove text IDs

- 1 Select the check boxes in front of the text IDs that you want to remove.
- 2 Choose the **Remove Selected Text ID(s)** button which is shown below the list of literals.
- 3 Choose the **Save** button to remove the text IDs from the translation file.

Style Sheet Editor

▪ About the Style Sheet Editor	96
▪ Creating a Folder for Your Own Style Sheets	96
▪ Invoking the Style Sheet Editor	96
▪ Defining the Location for Your Own Style Sheets	97
▪ Creating a New Style Sheet	98
▪ Opening an Existing Style Sheet	100
▪ Changing a Style Sheet	101
▪ Overview of Variables	103
▪ Regenerating Your Own Style Sheet from the Style Sheet Template	104
▪ Using a Version Control Tool	104

About the Style Sheet Editor

All controls that are contained inside the control library are rendered using a style sheet. Ajax Developer delivers a variety of predefined styles but also allows to you to create your own styles sheets.

The Style Sheet Editor simplifies the creation of your own style sheets: on the one hand, you can define the very basic style elements (main colors to be used), and on the other hand, you can change a controls' style definition on the lowest level.

For information on how to define a style sheet in the Layout Painter, see [Defining a Style Sheet](#).

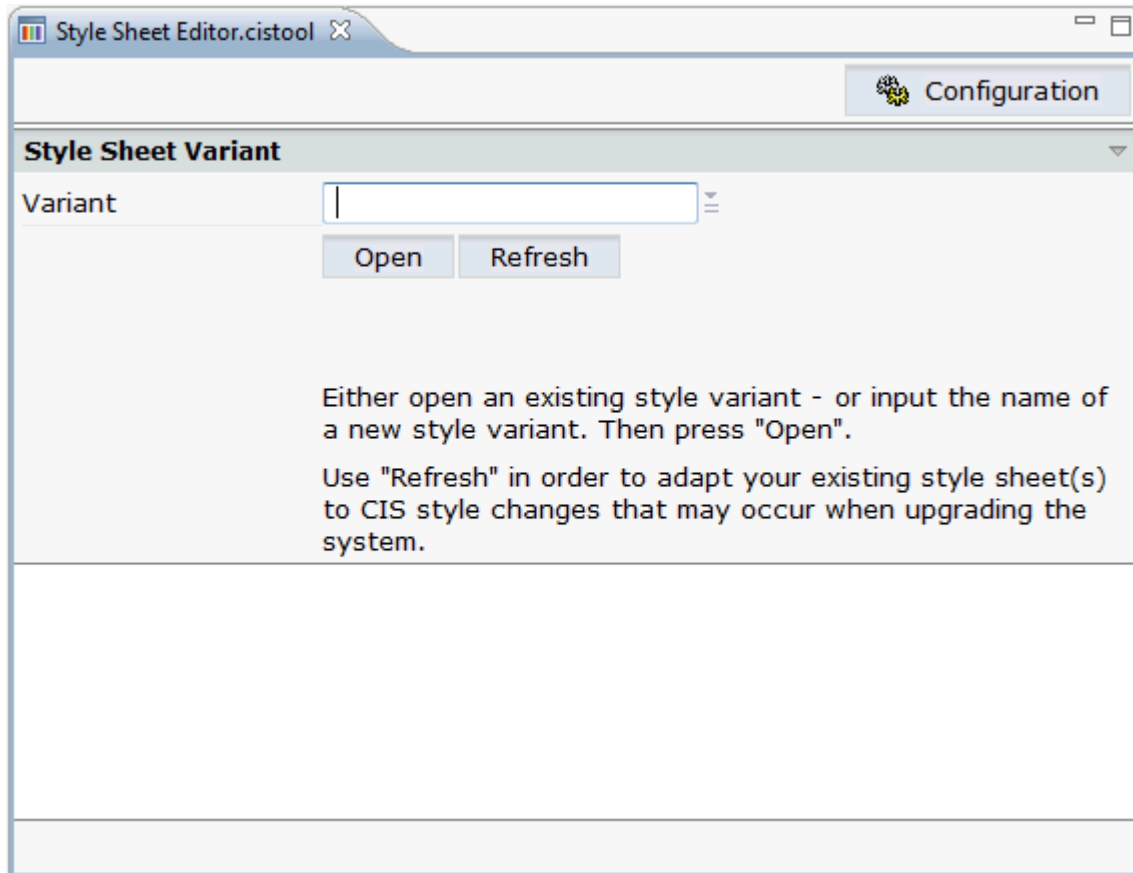

For further information on style sheets, see *Adapting the Look & Feel in Special Development Topics*.

Creating a Folder for Your Own Style Sheets

Style sheets are part of your application's user interface and should therefore be maintained in a user interface component. It is good practice to maintain your project-specific style sheets in a subfolder of a user interface component, for example, in a subfolder named *styles*.

Invoking the Style Sheet Editor

When you invoke the Style Sheet Editor, the following is shown:

▶ **To invoke the Style Sheet Editor**

- 1 In the **Navigator** view, select the project for which you want to invoke the Style Sheet Editor.
- 2 Invoke the context menu and from the **Ajax Developer** menu, choose **Style Sheet Editor**.

Defining the Location for Your Own Style Sheets

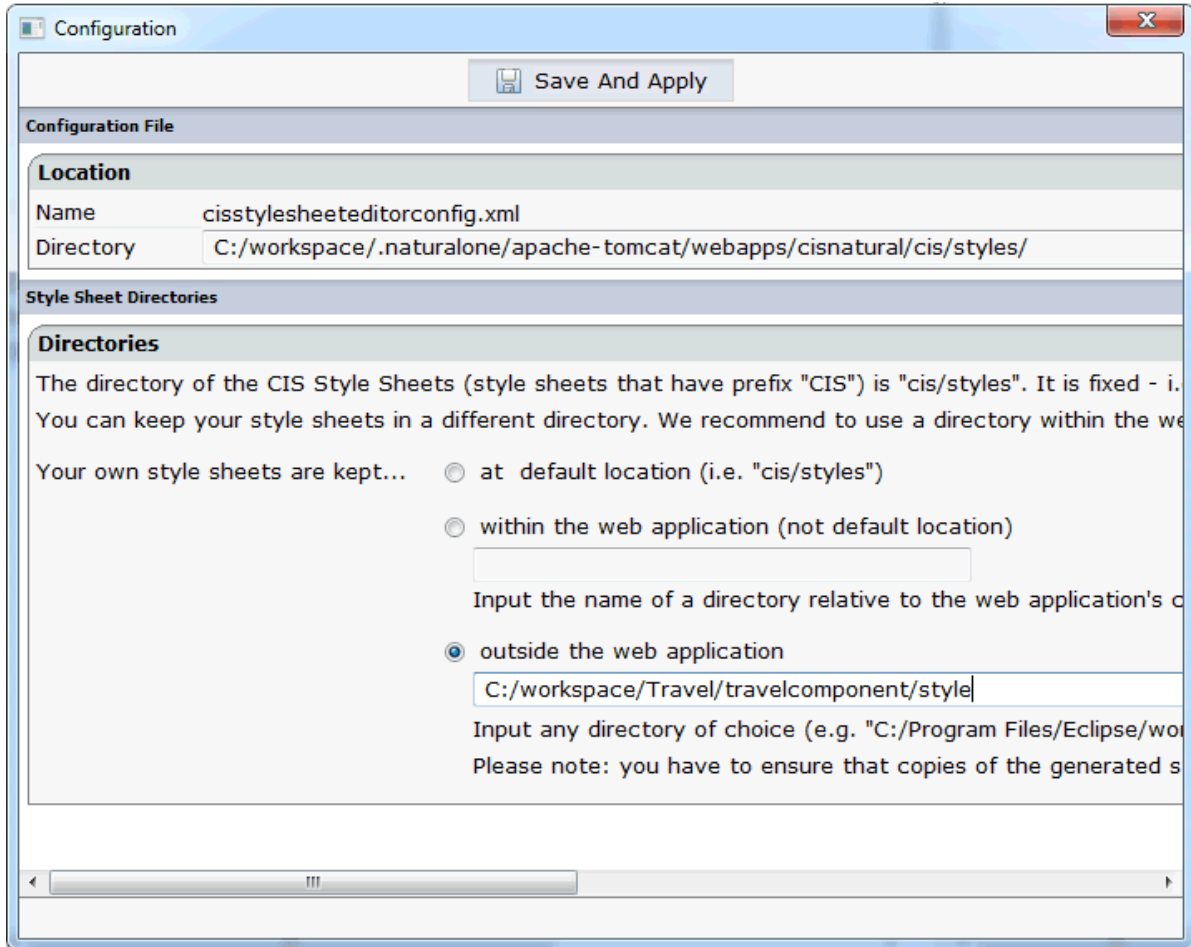

Ajax Developer provides a set of predefined style sheets. In a NaturalONE installation, these style sheets are available in the directory `<eclipse-workspace>/naturalone/apache-tomcat/webapps/cisnatural/cis/styles`. Otherwise, these style sheets are located in `<your-webapplication>/cis/styles`. The names of the predefined style sheets have the prefix "CIS_".

When you create your own style sheets, first copy the predefined style sheets into the style sheet folder of your user interface component.

▶ **To define the location for your own style sheets**

- 1 Choose the **Configuration** button which is shown in top right of the Style Sheet Editor.

- 2 In the resulting dialog box, choose the option button **outside the web application**.
- 3 Specify the absolute path to your style sheet folder, for example, `<eclipse-workspace>/Travel/travelcomponent/styles`.

- 4 Choose the **Save and Apply** button.

Creating a New Style Sheet

When you create and save a new style sheet, it is written to the directory that has been defined in the **Configuration** dialog.

You can determine that your new style sheet is immediately applied to the current session.

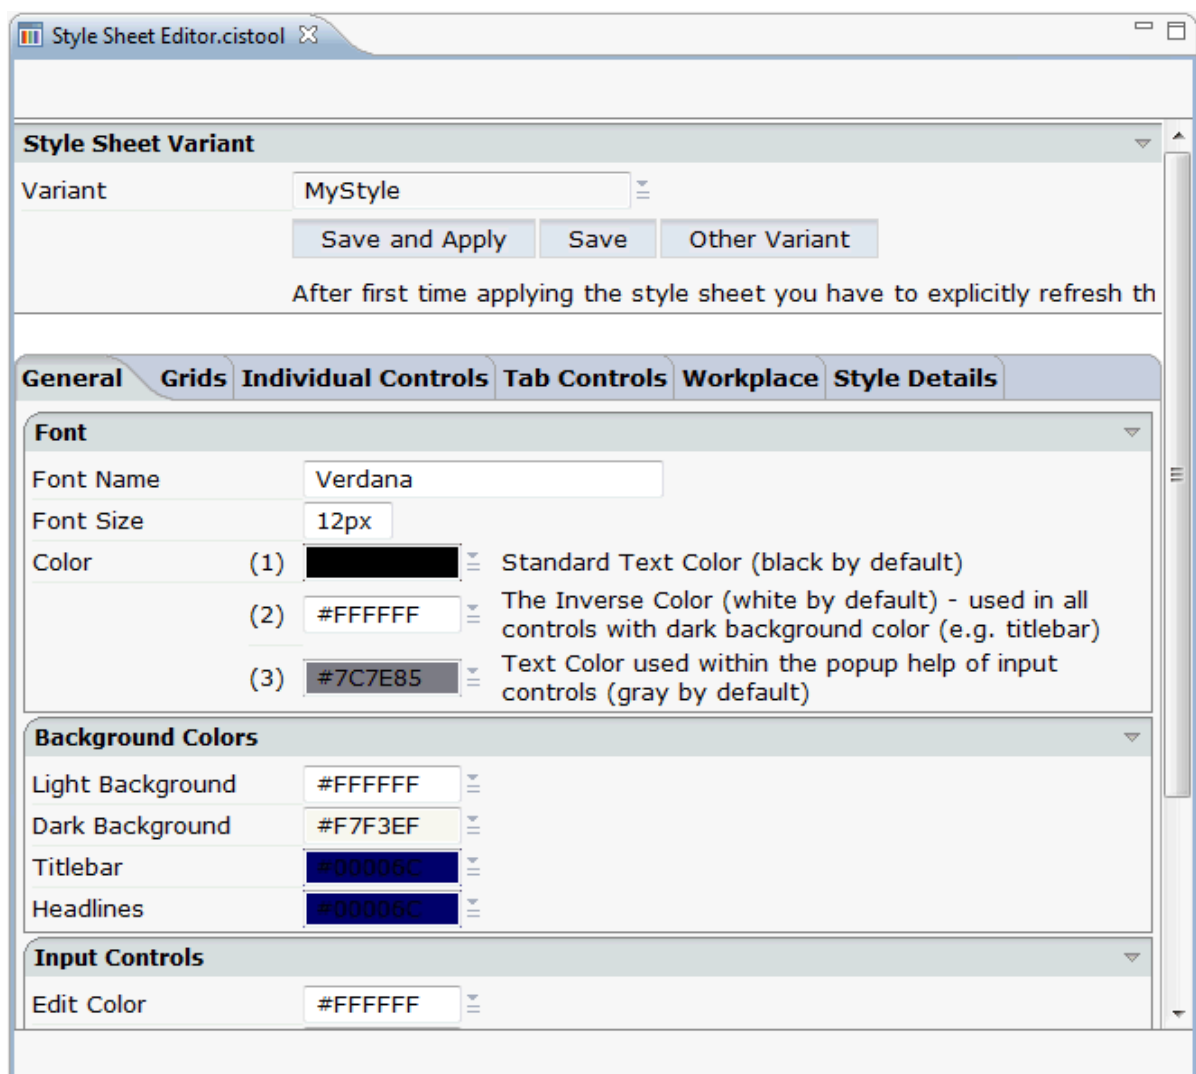

Note: By default, your pages are rendered with the `CIS_DEFAULT` style sheet which is one of Ajax Developers' predefined style sheets.

▶ **To create a new style sheet**

- 1 In the **Variant** drop-down list box, enter the name for your new style sheet.
- 2 Choose the **Open** button.

The following is shown:

- 3 Modify the values on the different tabs according to your requirements. See [Changing a Style Sheet](#) for information on the **Style Details** tab.

 **Note:** When you choose the **Other Variant** button, the dialog is shown again which appears when you invoke the Style Sheet Editor. You can then open another style sheet or create a new style sheet. If you have not saved your input previously, it is lost.

- 4 To save your changes, choose either the **Save** button or the **Save and Apply** button.

When you save a new style sheet for the first time, it is created in your style sheet directory with the extension `css`.

When you choose the **Save and Apply** button, the style sheet file is immediately applied to the current session.

Opening an Existing Style Sheet

When you open an existing style sheet, you can modify it according to your requirements and/or immediately apply the style sheet to the current session.

▶ To open an existing style sheet

- 1 From the **Variant** drop-down list box, choose the name of the style sheet that you want to open.

Note: In addition to the style sheet names, the drop-down list box also shows the paths to the corresponding files in the file system.

- 2 Choose the **Open** button.

The dialog with the style sheet definitions appears.

- 3 Modify the values on the different tabs according to your requirements. See [Changing a Style Sheet](#) for information on the **Style Details** tab.

Note: When you choose the **Other Variant** button, the dialog is shown again which appears when you invoke the Style Sheet Editor. You can then open another style sheet or create a new style sheet. Any changes that you have applied after the last save are lost.

- 4 To save your changes, choose either the **Save** button or the **Save and Apply** button.

When you choose the **Save and Apply** button, the style sheet file is immediately applied to the current session.

Changing a Style Sheet

Ajax Developer provides an internal style template in which all the default style information is kept. A newly created style sheet is identical to this template. All style updates that you apply to your style sheet are stored within a separate file which has the extension *info*. For example, if you named your style sheet "MyStyle", your style sheet folder contains the file *MyStyle.info*.

 **Note:** The style sheet folder also contains GIF files. They are generated according to your specifications for background, font, border color, etc. Each style sheet has thus individual GIF files. When you modify, for example, a color setting, new GIF files are generated which overwrite the previous GIF files.

When you edit a style sheet, you define the standard settings such as the font size on the **General** tab. All of the settings defined on the **General** tab are then assigned to individual controls on the **Style Details** tab via the corresponding variable (for example, @@FONTSIZE@@). See [Overview of Variables](#).

*	Attribute	Value
<input type="checkbox"/>	font-family	@@FONT@@
<input type="checkbox"/>	font-size	@@FONTSIZE@@
<input type="checkbox"/>	color	@@FONTCOLOREDARK@@

► To change a style sheet

- 1 Go to the **Style Details** tab.
- 2 Expand the tree on the left and select the name of a style sheet class.

The attributes for the selected class are shown on the right.

- 3 Select the attribute that you want to change.

The line is marked as selected and the attribute name and value are now shown in the text boxes at the bottom.

- 4 Specify another value for the attribute in the text box at the bottom. For example, if you want to define another color, you can define a color value such as #FF0000 (instead of @@FONTCOLORDARK@@).

You can also define a different name for a property. As soon as you choose the **Update** button, a new entry is created in the style sheet. This entry must be a valid CSS style sheet definition. For example, when you change the attribute name from `color` to `background-color`, this is a valid definition. When you specify an invalid attribute name, this will not have any effect. For example, when you change the attribute name from `color` to `hello`, this will not have any effect even though the new entry `hello @@FONTCOLORDARK@@` will be created.

- 5 Choose the **Update** button.

When you have changed a default entry of the style template, the changed information is now shown in bold in an additional line. For example:

*	Attribute	Value
<input type="checkbox"/>	color	#FF0000
<input type="checkbox"/>	font-family	@@FONT@@
<input type="checkbox"/>	font-size	@@FONTSIZE@@
<input type="checkbox"/>	color	@@FONTCOLORDARK@@

Notes:

1. If you do not want to take over a property from the style sheet template, specify "DELETE" as the attribute value and choose the **Update** button. All attributes that are marked with "DELETE" are not included in your style sheet.
2. If you want to take back a style update (that is: a change which is indicated by a bold line), delete the corresponding attribute value (that is: set it to blank) and choose the **Update** button. The bold line will disappear.

Overview of Variables

The following variables can be defined on the [Style Details](#) tab:

@@FONTCOLORDARK@@
@@FONTSIZE@@
@@FONT@@
@@LIGHTBACKGROUND@@
@@HEADLINEBACKGROUND@@
@@BORDERCOLOR@@
@@DARKBACKGROUND@@
@@TITLEBARBACKGROUND@@

Regenerating Your Own Style Sheet from the Style Sheet Template

From release to release, new controls are added to the control library. As a consequence, the style sheet template is typically enhanced with every new control (for example, new style classes are added). As your style changes are kept in a separate file which has the extension *info*, your style sheet can easily include the enhancements. You just have to regenerate your own style sheet file.

Important: After the installation of a new Ajax Developer build, you have to regenerate your own style sheet(s).

▶ To regenerate your own style sheet

- 1 From the **Variant** drop-down list box, select the name of your style sheet.
- 2 Choose the **Refresh** button.

The following command buttons are now shown: **Selected Variant** and **All Variants**.

- 3 Choose the **Selected Variant** button.

Note: Choose the **All Variants** button if you want to regenerate all existing style sheets.

Using a Version Control Tool

If you want to secure your style sheets with a version control tool, it is sufficient to keep the files with the extension *info* under version control. The actual style sheet file (with the extension *css*) is just a generation result out of the *INFO* file.

IV Control Editor

You use the Control Editor to build your own custom controls.

The description of the Control Editor is organized under the following headings:

[Using the Control Editor](#)

[Defining a Control](#)

[Examples](#)

Note: Before you proceed with the information in this documentation, it is recommended that you first become familiar with the control development with Ajax Developer. For detailed information, see *Custom Controls*.

11

Using the Control Editor

▪ Invoking the Control Editor	108
▪ Creating an Editor Extension	109
▪ Adding a Control to an Editor Extension	111
▪ Adding a Data Type to an Editor Extension	112
▪ Deleting a Control or Data Type	115
▪ Saving an Editor Extension	115
▪ Opening an Editor Extension	116

Invoking the Control Editor

When you invoke the Control Editor, a dialog appears which shows a list of all editor extensions. These are the XML files with the prefix "editor_" which are stored in the central directory `<your-webapplication>/cis/config` and in the subdirectories `cisconfig` of your user interface components. A single editor extension may contain multiple controls. Ajax Developer comes along with a set of predefined editor extensions.

If you start the Control Editor for the first time, cancel the dialog and create a new editor extension. See [Creating an Editor Extension](#).

 **Important:** Never touch an editor extension file you do not own. Develop your controls within your own extension.

▶ To invoke the Control Editor

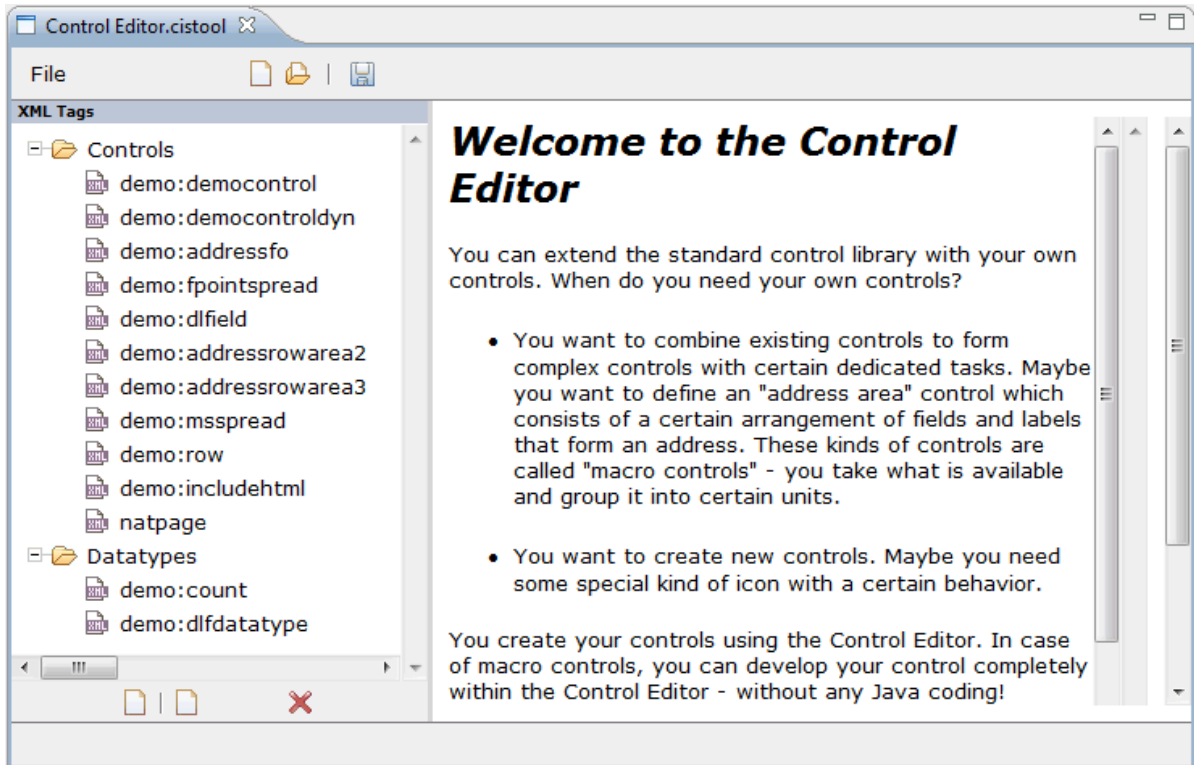

- 1 In the **Navigator** view, select the project for which you want to invoke the Control Editor.
- 2 Invoke the context menu and from the **Ajax Developer** menu, choose **Control Editor**.

A dialog appears, listing all available editor extensions.

- 3 Choose the editor extension that you want to open.

The contents of the editor extension are loaded into the Control Editor. Example:

You can now edit your editor extension as described in the remainder of this section.

 **Note:** You can also open an editor extension as described in [Opening an Editor Extension](#).

Creating an Editor Extension

When you create a new editor extension, you can choose whether to store it in the central directory `<your-webapplication>/cis/config/` or in the subdirectory `cisconfig` of your user interface component.

▶ To create an editor extension

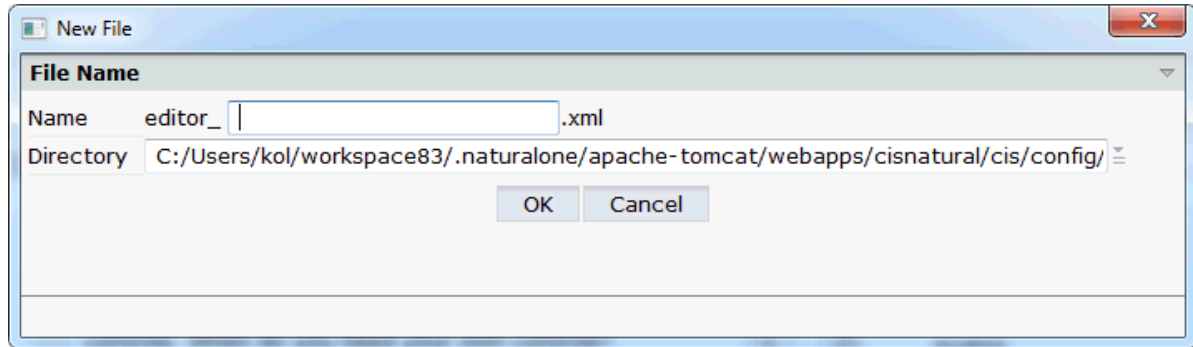

- 1 From the **File** menu of the Control Editor, choose **New**.

Or:

Choose the following button from the toolbar of the Control Editor.

The following dialog appears.

- 2 Enter the name of your editor extension (for example, "mycontrols").
- 3 From the **Directory** drop-down list box, select the directory in which the new editor extension is to be stored.

The drop-down list box shows the full path names. The names of your user interface components are shown in the path names.

- 4 Choose the **OK** button.

The name of your new editor extension is composed of the prefix "editor_" and the name you have specified (for example, *editor_mycontrols.xml*). The extension is always *xml*.

The following empty nodes are now shown.

You can now add **controls** and **data types** as described below.

Adding a Control to an Editor Extension

A control consists of the control's definition (attributes and positioning) and its corresponding tag handler (Java class).

When defining macro controls, you do not have to write your own tag handler class. You can define the inner structure directly within XML (XML/protocol extension).

When defining completely new controls which implement their own HTML/JavaScript, you must also implement a corresponding tag handler in order to generate your own HTML/JavaScript code.

▶ To add a control

- 1 Choose the first button which is shown below the tree of XML tags (when you move the mouse over this button, the tooltip "New Control" appears):

The following dialog appears.

- 2 Enter a name for the new control.

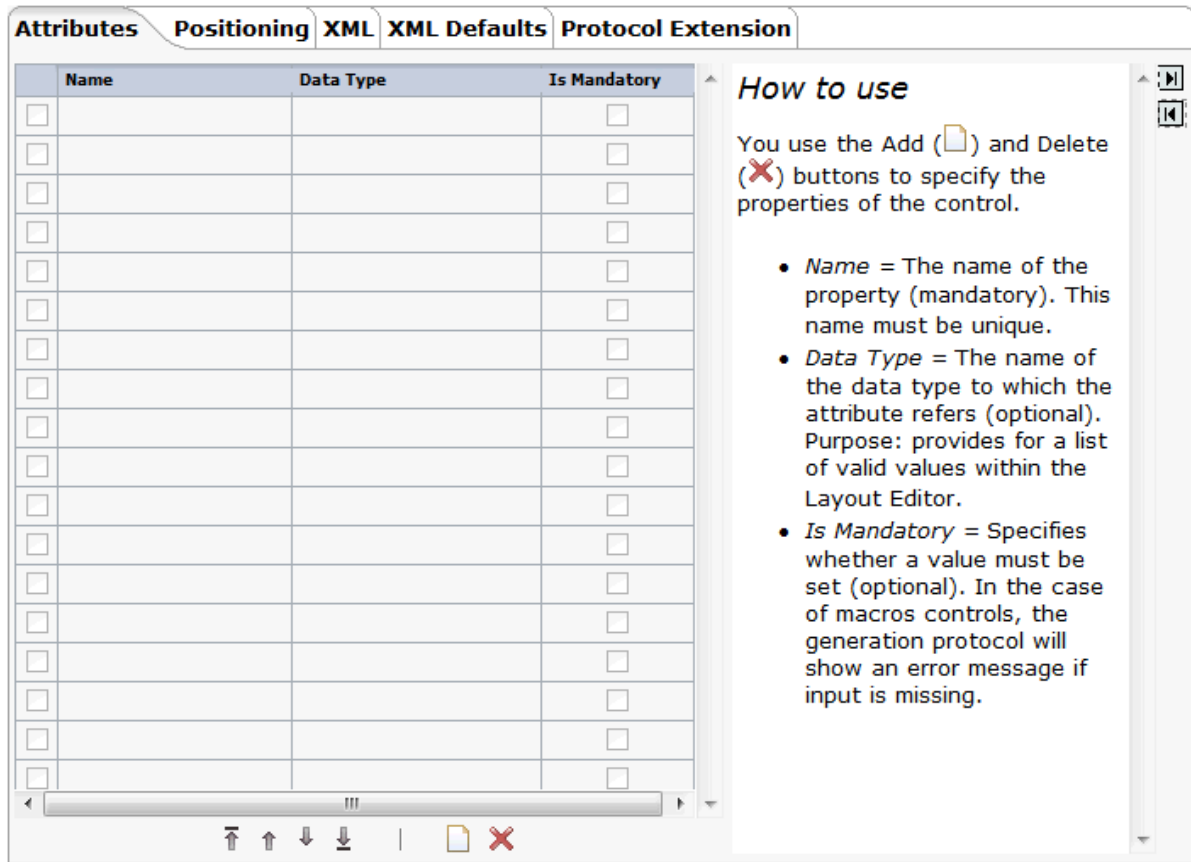

The name of a control must be unique within your control library. Therefore, you have to prefix the control name with the name of the control library: "`<control-library-name>:<control-name>`". See also *Library Concept in Custom Controls*.

- 3 Choose the **OK** button.

The new control is inserted in the **Controls** node. If the **Controls** node already contains controls, each new control is automatically inserted at the bottom of the list.

- 4 Select the new control in the tree.

The following information is shown.

Using the buttons  and  you can hide and show the help information in this dialog.

- 5 Specify all required information on the different tabs. See [Defining a Control](#) for detailed information on these tabs.

See also [Examples](#).

Adding a Data Type to an Editor Extension

A data type defines a list of valid values. The properties of your controls can have data types. This is optional.

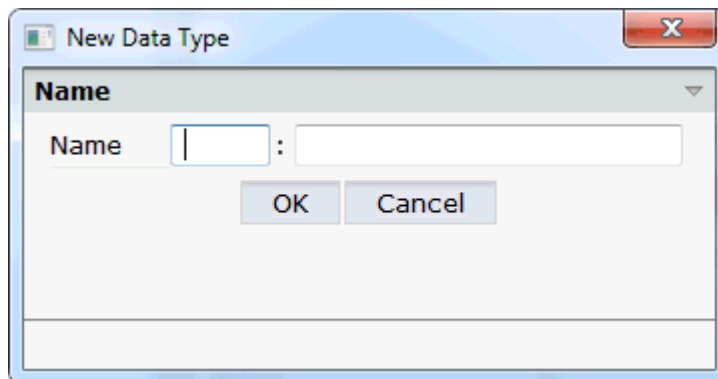

A set of predefined data types (such as `align` or `boolean`) is provided. You can use them within your control's definition. They are defined in the editor configuration file `editor.xml`. If there is no appropriate data type for your purpose, you can create your own data type.

▶ **To add a data type**

- 1 Choose the second button which is shown below the tree of XML tags (when you move the mouse over this button, the tooltip “New Datatype” appears):

The following dialog appears.

- 2 Enter a name for the new data type.

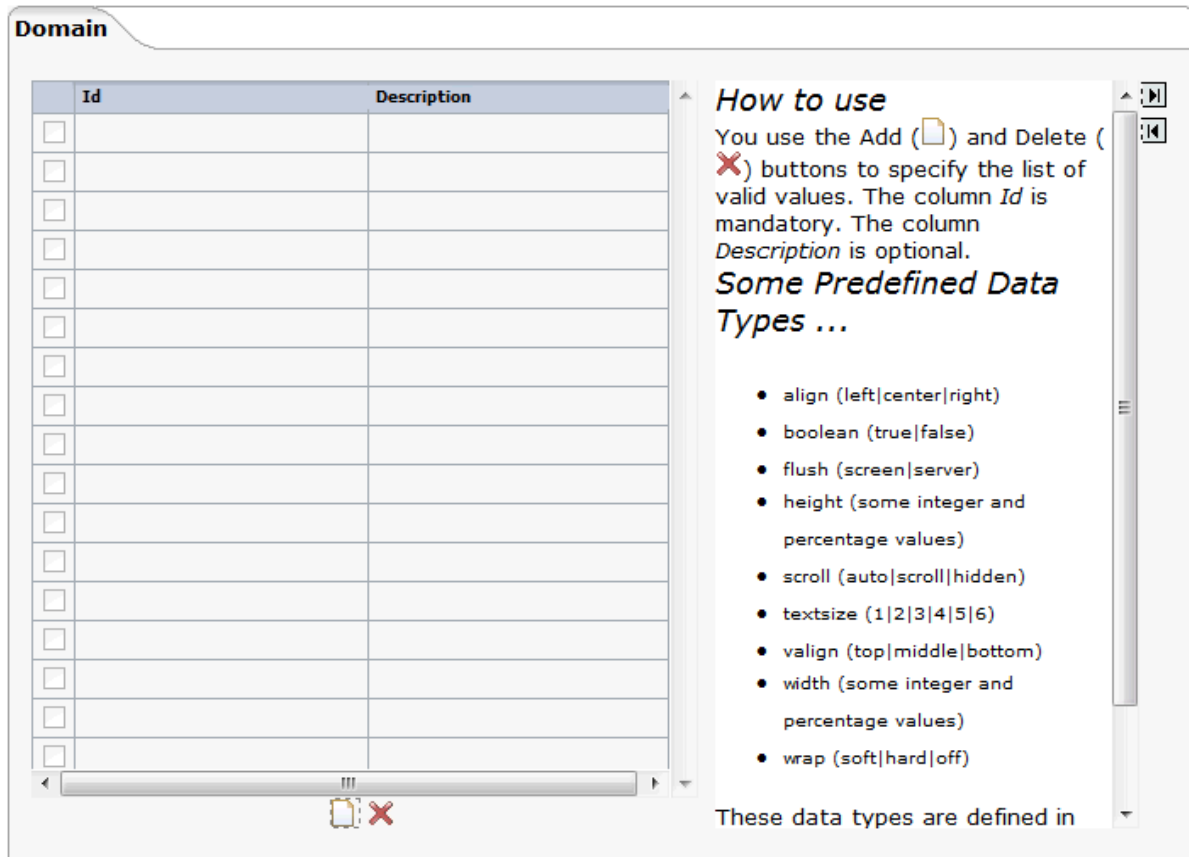

The name of a data type must be unique within your control library. Therefore, you have to prefix the data type name with the name of the control library: "`<control-library-name>:<data-type-name>`".

- 3 Choose the **OK** button.

The new data type is inserted in the **Datatypes** node. If the **Datatypes** node already contains data types, each new data type is automatically inserted at the bottom of the list.

- 4 Select the new data type in the tree.

The following information is shown.

Using the buttons  and  you can hide and show the help information in this dialog.

The following buttons are provided on this tab:

Button	Description
	Adds an empty line in which you can specify a data type.
	Deletes the selected data type(s).

- 5 Use the  button to add one or more empty lines and specify the following:

Id

The name of the data type.

Description

Optional. A short description of your data type.

See also [Examples](#).

Deleting a Control or Data Type

You can delete any controls or data types that are shown in the tree of XML tags.

▶ **To delete a control or data type**

- 1 In the tree of XML tags, select the control or data type that you want to delete.
- 2 Choose the following button which is shown below the tree of XML tags:

You are not asked to confirm the deletion.

Saving an Editor Extension

When you save an editor extension, all of your changes in the Control Editor are saved. This includes all controls and data types that you have added or changed.

▶ **To save an editor extension**

- From the **File** menu of the Control Editor, choose **Save**.

Or:

Choose the following button from the toolbar of the Control Editor.

The status bar of the Control Editor shows the name of the file (including the path) to which the information has been written.

Tip: If the path is longer than can be shown in the status bar, click on the status bar. You can then find out the complete path and file name in a separate dialog.

Opening an Editor Extension

You can open any editor extension that is stored in the central directory `<your-webapplication>/cis/config/` or in the subdirectories `cisconfig` of your user interface components.

▶ To open an editor extension

- 1 From the **File** menu of the Control Editor, choose **Open**.

Or:

Choose the following button from the toolbar of the Control Editor.

Note: When your latest changes in the Control Editor have not yet been saved, you are asked whether you want to save them.

The **Open File** dialog appears.

- 2 Choose the editor extension that you want to open.

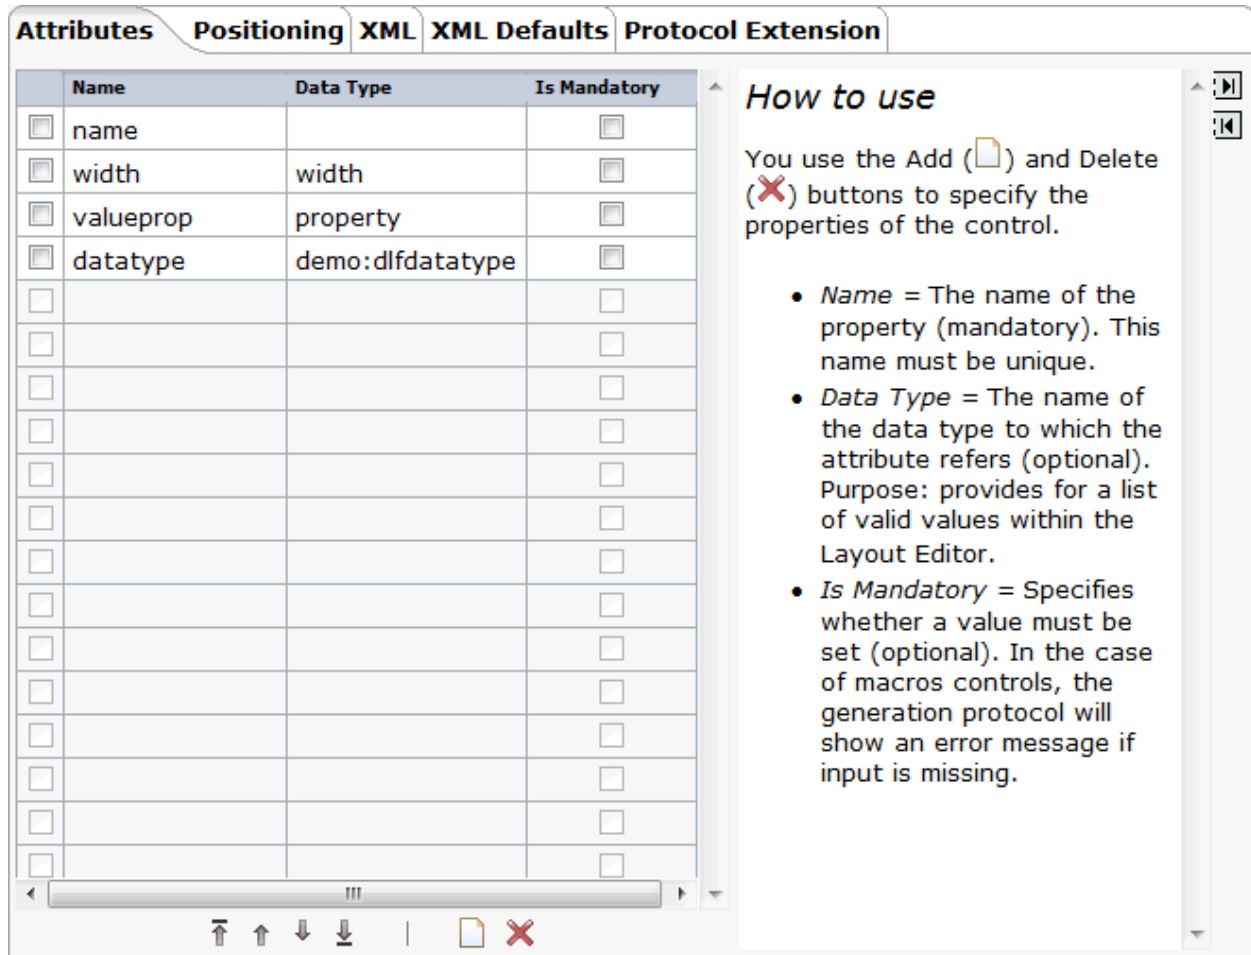

The contents of the editor extension are loaded into the Control Editor.

12 Defining a Control

▪ Attributes	118
▪ Positioning	119
▪ XML	121
▪ XML Defaults	122
▪ Protocol Extension	123

Attributes

The **Attributes** tab is used to specify the list of attributes.

The following buttons are provided below the list of attributes:

Button	Description
	Moves the selected attribute(s) up to first position in the list.
	Moves the selected attribute(s) up to the previous position in the list.
	Moves the selected attribute(s) down to the next position in the list.
	Moves the selected attribute(s) down to last position in the list.
	Adds an empty line in which you can specify a property.
	Deletes the selected attribute(s).

To define a property, use the  button to add an empty line and specify the following information in this line:

Name

The name of a property. The name must be unique within this attribute list.

Data Type

Optional. The name of a data type to which the attribute refers. The data type can be an Application Designer data type (see the data type definitions in the file *editor.xml*) or a user-defined data type.

Is Mandatory

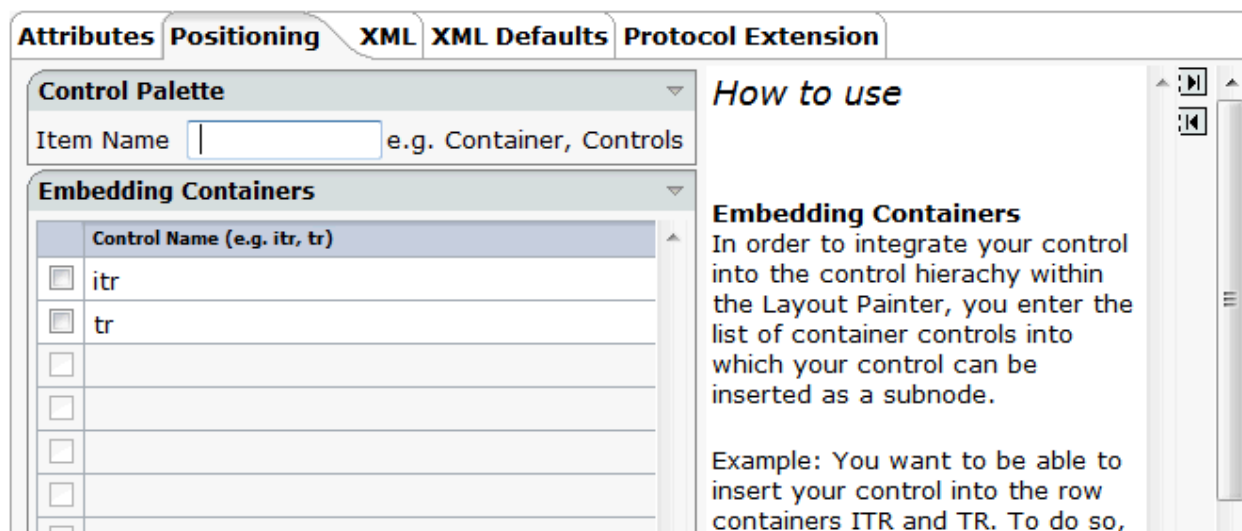

Optional. When this check box is selected, a value for the corresponding attribute must be set.

In the case of macro controls, the generation protocol will show an error message if input is missing.

Positioning

The **Positioning** tab is used to specify the following:

- the section of the controls palette which is to contain the control,
- the containers in which the user will be able to insert the control, and
- the subcontrols which the user can insert into the control.

The following buttons are provided on this tab:

Button	Description
	Adds an empty line in the corresponding list.
	Deletes the selected control(s) from the corresponding list.

Specify the following information:

Controls Palette

The section of the controls palette in which your new controls are to be included. You can either specify an existing section such as **Controls**, or you can specify a new section.

For example, when you specify the name "MyControls", you have to choose the **MyControls** button in the controls palette to display your controls.

Embedding Containers

This list determines the availability in the Layout Painter.

Use the  button to add one or more empty lines and specify the names of the containers (such as ITR or TR) into which your new control can be inserted as a subnode. If specify your own controls, do not forget to use the library prefix.

In the Layout Painter, the new control can then be selected from:

- **Context Menu**

The new control will be offered for selection in the Layout Painter when you invoke the context menu for an embedding container control.

For example, when you define a new control with the name "test:mycontrol" and define the ITR control as an embedding container, this control will be available as follows:

- **Add as first Subnode > Extensions > test:mycontrol**
- **Add as last Subnode > Extensions > test:mycontrol**

- **Controls Palette**

The new control will be available in the controls palette of the Layout Painter. It is shown when you open the corresponding section of the controls palette. For example, when you have defined that control is to appear in the **MyControls** section, you have to choose the **MyControls** button.

The Layout Painter will use a default image in the controls palette. However, you can assign your own image; in this case, you have to observe the following rules:

- The image must be a GIF file.
- The name of the image must have the following structure:

`ctrl<LIBRARY-NAME>_<CONTROL-NAME>.gif`

For example:

ctrlTEST_MYCONTROL.gif

- The image must be stored in the directory `<your-webapplication>/cis/config/controlimages`.
- The preferred width is 16 pixels and the preferred height is 16 pixels.

Sub Controls

Your control can be a container itself (for example, you want to be able to insert the standard ICON control into your container). In this case, you enter the list of the subcontrols here.

Use the  button to add one or more empty lines and specify the names of the subcontrols (such as ICON). If you specify your own controls, do not forget to use the library prefix.

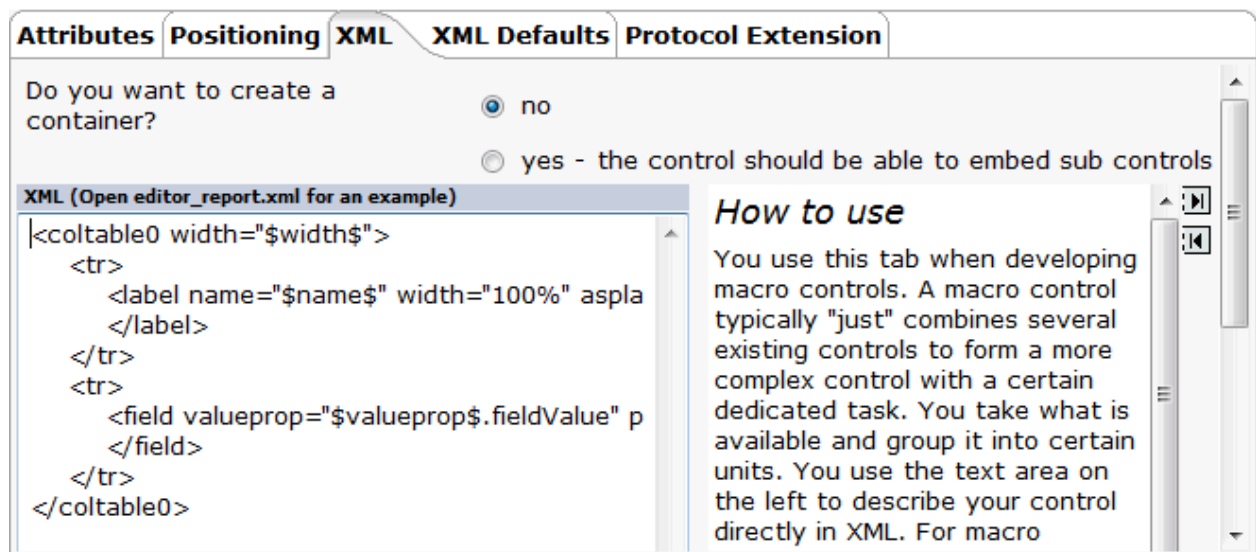

XML

The **XML** tab is used to specify a macro control.

Typically, your control combines existing controls to form a more complex control with a certain dedicated task. You take what is available and group it into certain units.

With a macro control, you compose your control directly in XML and therefore do not need to provide for a tag handler class.

See also [Defining a Macro Control](#) in the *Examples* section.

The screenshot shows a software interface with several tabs: **Attributes**, **Positioning**, **XML** (selected), **XML Defaults**, and **Protocol Extension**. Below the tabs, there is a question: "Do you want to create a container?" with two radio button options: "no" (selected) and "yes - the control should be able to embed sub controls". Below this is a text area titled "XML (Open editor_report.xml for an example)" containing the following XML code:

```
<coltable0 width="$width$" >
  <tr>
    <label name="$name$" width="100%" aspla
  </label>
  </tr>
  <tr>
    <field valueprop="$valueprop$.fieldValue" p
  </field>
  </tr>
</coltable0>
```

To the right of the XML text area is a section titled "How to use" with the following text:

You use this tab when developing macro controls. A macro control typically "just" combines several existing controls to form a more complex control with a certain dedicated task. You take what is available and group it into certain units. You use the text area on the left to describe your control directly in XML. For macro

Specify the following information:

Do you want to create a container?

Select one of the following option buttons:

- **no**
When this button is selected, your control cannot embed other controls. `BUTTON` is an example of such a control.
- **yes**
When this button is selected, your control is a container control which can embed other controls. `ITR` and `ROWAREA` are examples of container controls.

XML

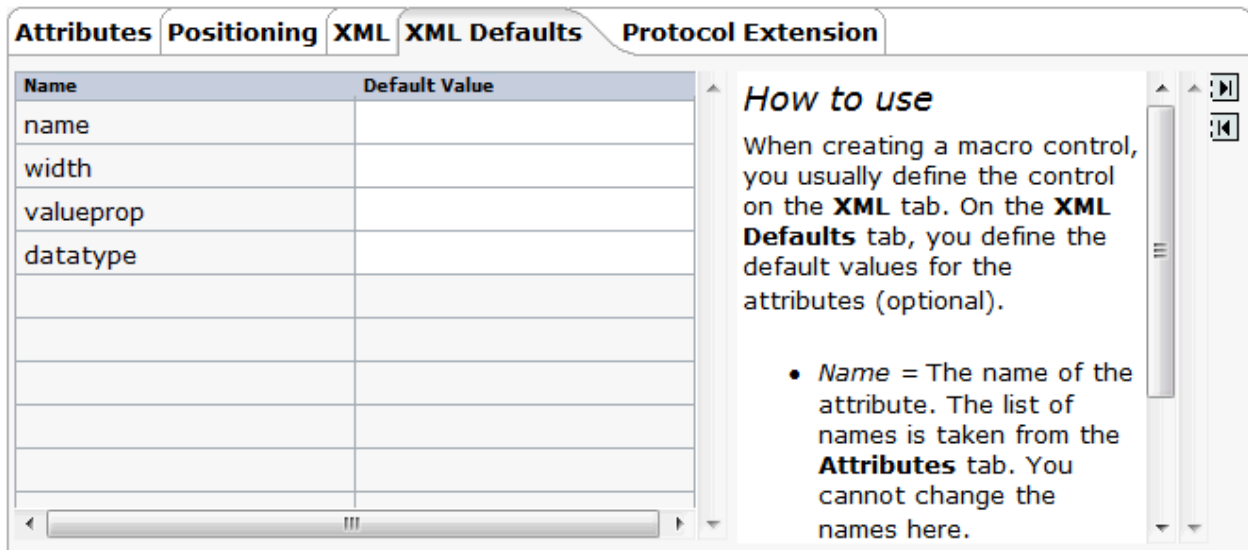

Enter your macro in this text box.

XML Defaults

Only applies to a macro control.

When you have entered a macro control on the **XML** tab, you can use the **XML Defaults** tab to define the default values for the attributes (optional).

All attributes that are currently defined on the **Attributes** tab are automatically provided on the **XML Defaults** tab.

Specify the following information:

Default Value

The default value will be used if the user does not specify a value.

Protocol Extension

Use the **Protocol Extension** tab only if you develop a macro control and do not provide a tag handler class. In this case, you can use this tab to append the referred properties and methods to the generation protocol. If you provide a tag handler class, you implement the addition of properties and methods to the generation protocol in the tag handler class instead.

See also [XML Definition for a Macro Control with a Server-Side Representative](#) in the *Examples* section.

The following buttons are provided on this tab:

Button	Description
	Adds an empty line in the corresponding list.
	Deletes the selected line(s) from the corresponding list.

Specify the following information:

Properties

Use the  button to add one or more empty lines and specify the following:

Name

The name of the adapter property that is used in your control.

Data Type

Optional. The data type of the property. This information is used in the Code Assistant (which is part of the Layout Painter) to generate appropriate property coding.

 **Note:** This has no meaning for custom controls in NATPAGE layouts.

Preset Value

Optional. The value that is set in your adapter when the page is loading.

Show in Code Assistant

When this check box is selected, the property appears in the Code Assistant. By default, this check box is selected.

You should only select this check box for the properties that must be provided by the adapter.

Note: This has no meaning for custom controls in NATPAGE layouts.

Methods

Use the  button to add one or more empty lines and specify the following:

Method Name

The name of the adapter method.

Show in Code Assistant

When this check box is selected, the method appears in the Code Assistant. By default, this check box is selected.

You should only select this check box for the methods that must be provided by the adapter.

Note: This has no meaning for custom controls in NATPAGE layouts.

JavaScript Libraries

Use the  button to add one or more empty lines and specify the following:

Source

The URL that points to your JavaScript library.

13 Examples

▪ About the Examples	126
▪ Defining a Control with a Corresponding Tag Handler	126
▪ Defining a Macro Control	129
▪ Additional Information	138

About the Examples

These examples assume that you expect the label of an input field not at the left of the field but above the field (two separate rows). Furthermore, you want to have several such fields within a single row (inline control).

For these examples, you will proceed as follows:

1. You create your own editor extension with the name *editor_test.xml*.

Important: Do not use the Application Designer editor extensions for your own controls. Place your own controls within your own extension file. Thus, there will be no conflicts when upgrading your installation to a newer build.

2. You build a control named DLFIELD (double line field) which will be available in the control library "test". Therefore, you have to name your control "test:dlfield". See also *Library Concept* in *Custom Controls*.
3. You define a macro control which determines that the control consists of two rows, one for the label and another for the field. The rows themselves are placed into a column container.

The composition of controls looks roughly like this:

```
COLTABLEO
TR
  LABEL
TR
  FIELD
```

Defining a Control with a Corresponding Tag Handler

The definition of a control with a corresponding tag handler is quite simple. It consists of

- the name of the control,
- the list of attributes, and
- the list of embedding container controls.

You will now define a control with the following properties: *name* (label name), *width* (width of column container) and *valueprop* (name of the adapter property to which the field is bound). The control will be available within the row containers TR and ITR.

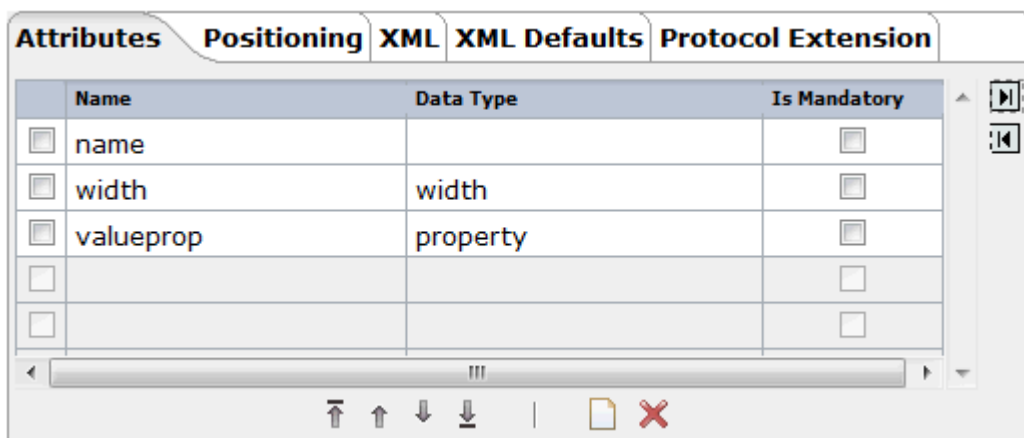

Note: For further information on the tag handler, see *Control Concept* in *Custom Controls*.

► To define a new control

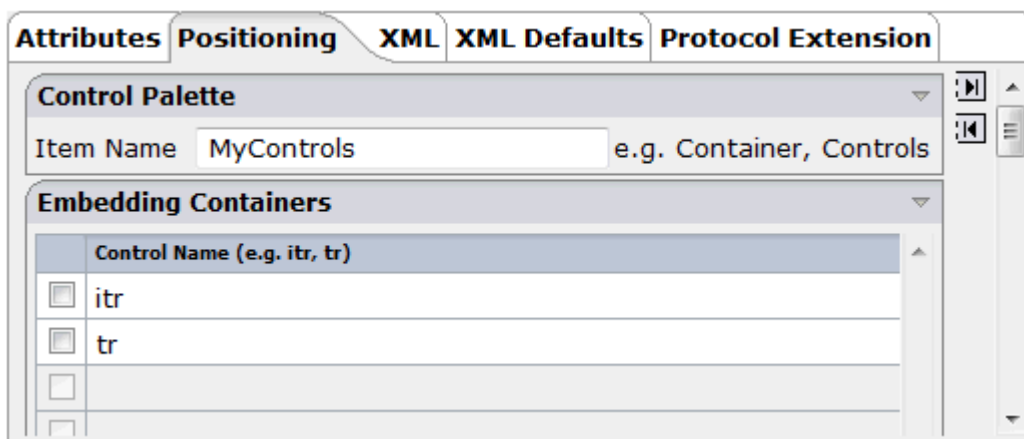

- 1 Invoke the Control Editor.
- 2 **Create your own editor extension** with the name *editor_test.xml*
- 3 **Add a new control** with the name "test:dlfield".

 **Note:** The editor extension *editor_demo.xml* contains a control with the name "demo:dlfield". When you have completed the example, your new "test:dlfield" extension should be similar to "demo:dlfield".

- 4 Select your new control in the tree.
- 5 To create the list of attributes, specify the following information on the **Attributes** tab:

- 6 Specify the following information on the **Positioning** tab:

This determines that your control can be selected from the **MyControls** section of the controls palette and that it can be inserted into the row containers TR and ITR.

- 7 Save your changes.
- 8 Have a look at the generated XML file (*editor_test.xml*). It should look as follows:

```
<?xml version="1.0" encoding="UTF-8"?>

<!--
Dynamic extension of editor.xml file.
-->

<controllibrary>
  <editor>

    <!--
    *****
    * DATATYPEs
    *****
    -->

    <!--
    *****
    * TAGs
    *****
    -->

    <!-- TEST:DLFIELD -->
    <tag name="test:dfield">
      <attribute name="name"/>
      <attribute name="width" datatype="width"/>
      <attribute name="valueprop" datatype="property"/>
      <taginstance>
      </taginstance>
      <protocolitem>
      </protocolitem>
    </tag>
    <tagsubnodeextension control="itr" newsubnode="test:dfield"/>
    <tagsubnodeextension control="tr" newsubnode="test:dfield"/>

    <taggroupsubnodeextension group="MyControls" newsubnode="test:dfield"/>

  </editor>
</controllibrary>
```

Defining a Macro Control

You can define a macro control as XML without any additional coding. The basic specification for a macro control defined as XML is the same as the specification for a control to which also a tag handler is applied. It consists of:

- the name of the control,
- the list of attributes, and
- the list of embedding container controls.

In addition, you define the following:

- the XML for the control,
- additional properties and methods (optional), and
- additional JavaScript libraries (optional).

With the definition of a macro control, you describe how the control is composed out of other controls. An attribute of the macro control can be referenced by enclosing the attribute name in "\$" characters (for example, "\$myattribute\$").

With a simple macro control, no further information is required.

Additional data (additional properties, methods, libraries) is only required if you want to bind the control to a so-called “server-side representative”. The control's properties and methods are bound to a dedicated Java class. Within this class, you typically encapsulate certain tasks/functionality used by the control.

The following topics are covered below:

- [XML Definition for a Simple Macro Control](#)
- [XML Definition for a Macro Control with a Server-Side Representative](#)

XML Definition for a Simple Macro Control

You will now continue with the "test:dlfield" control from the previous example.

You will add an XML definition to the "test:dlfield" control which defines the following:

- The control consists of a row for the label and a second row for the field.
- The rows themselves are placed into a column container.
- The property `width` is delegated to the column container. The label and field have a width of 100%.
- The property `name` is delegated to the corresponding property of the label.

- The property `valueprop` is delegated to the corresponding property of the field.

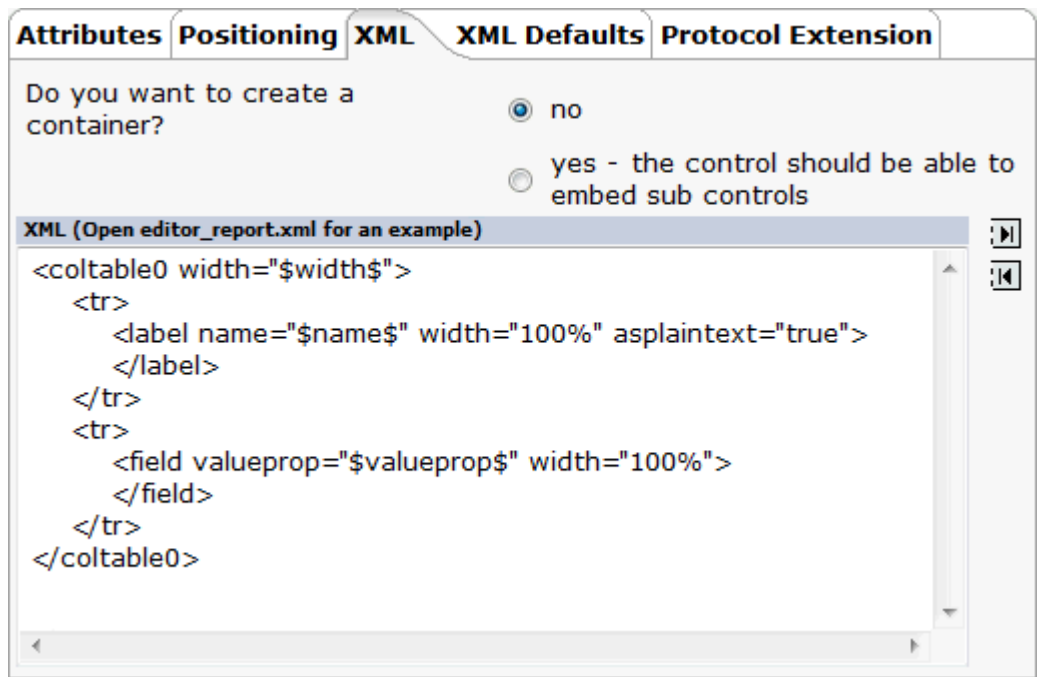

The XML for the macro control looks like this:

```
<coltable0 width="$width$">
  <tr>
    <label name="$name$" width="100%" asplaintext="true">
    </label>
  </tr>
  <tr>
    <field valueprop="$valueprop$" width="100%">
    </field>
  </tr>
</coltable0>
```

► **To define the XML of the macro control**

- 1 Specify the above XML on the **XML** tab of the "test:dfield" control.

The tab should now look as follows:

- 2 Save your changes.
- 3 Have a look at the generated XML file (*editor_test.xml*). It should now look as follows:

```

<?xml version="1.0" encoding="UTF-8"?>

<!--
Dynamic extension of editor.xml file.
-->

<controllibrary>
  <editor>

    <!--
    *****
    * DATATYPEs
    *****
    -->

    <!--
    *****
    * TAGs
    *****
    -->

    <!-- TEST:DLFIELD -->
    <tag name="test:dfield">
      <attribute name="name"/>
      <attribute name="width" datatype="width"/>
      <attribute name="valueprop" datatype="property"/>
      <taginstance>
        <coltable0 width="$width$">
          <tr>
            <label name="$name$" width="100%" asplaintext="true">
            </label>
          </tr>
          <tr>
            <field valueprop="$valueprop$" width="100%">
            </field>
          </tr>
        </coltable0>
      </taginstance>
      <protocolitem>
      </protocolitem>
    </tag>
    <tagsubnodeextension control="itr" newsubnode="test:dfield"/>
    <tagsubnodeextension control="tr" newsubnode="test:dfield"/>

    <taggroupsubnodeextension group="MyControls" newsubnode="test:dfield"/>

  </editor>
</controllibrary>

```

The control is now ready for use. The Layout Painter will offer the control for the containers ITR and TR.

XML Definition for a Macro Control with a Server-Side Representative

This example demonstrates how to build a macro control that refers to a server-side representative.

The server-side representative class `DLFIELDInfo` described below is specific for custom controls used within PAGE layouts. In addition, the Code Assistant support described below is only available in PAGE layouts.

For NATPAGE layouts, you can also implement server-side representative classes. These are the so-called “binding classes” (see also *Binding Concept* in the *Custom Controls* documentation which is part of the NaturalONE documentation).

It is important that the server-side representative classes for controls in PAGE layouts are different from the binding classes of custom controls in NATPAGE layouts. For binding classes of custom controls used within NATPAGE layouts, see the examples in the **njxdemos**.

You will now extend the "test:dlfield" control from the previous example as follows:

- If the field is used to enter a country or language, it provides a value help.
- For reuse, the computation of valid values is encapsulated within a server-side representative (Java class `DLFIELDInfo`).
- The field (i.e. the properties `valueprop` and `popupprop`) is bound to properties of class `DLFIELDInfo`.

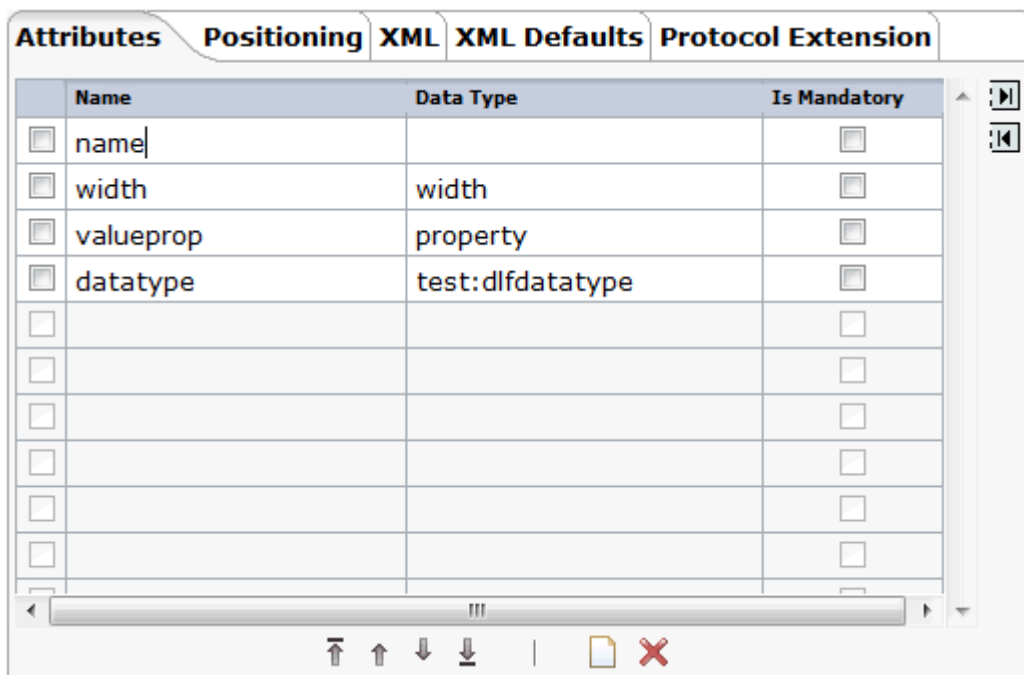

Thus, the page adapter just has to provide for a `DLFIELDInfo` object; it does not have to compute the value help by itself.

► To define a macro control with a server-side representative

- 1 **Add a new data type** with the name "test:dlfdatatype".
- 2 Select the new data type in the tree.
- 3 Specify the following values on the **Domain** tab:

- 4 Select the control "test:dlfield" in the tree.
- 5 On the **Attributes** tab, add the attribute datatype and define "test:dlfdatatype" as the data type.

Until now, you have used the attribute `valueprop` to bind the field's input value to an adapter property.

Using the server-side representative concept, the adapter now provides a property (referenced by the property `valueprop`) that returns an instance of such a representative (`DLFIELDInfo`). The field value and the value help are handled within that class. The following shows the coding of the class `DLFIELDInfo`:

```
package com.softwareag.cis.test35;

import com.softwareag.cis.server.util.ValidValueLine;
import java.util.*;
import com.softwareag.cis.server.*;
import com.softwareag.cis.server.util.*;
import com.softwareag.cis.util.*;

public class DLFIELDInfo
{
    private final static String ML_APP = "release35";
    private Adapter m_adapter;

    //Constructor

    public DLFIELDInfo(Adapter adapter)
    {
        m_adapter = adapter;
    }

    // -----
    // properties
    // -----

    // property >fieldValue<
    String m_fieldValue;
    public String getFieldValue() { return m_fieldValue; }
    public void setFieldValue(String value) { m_fieldValue = value; }

    // property >hasPopupHelp<
    public boolean getHasPopupHelp()
    {
        return m_fieldDatatype != null &&
            m_fieldDatatype.length() != 0;
    }

    // property >fieldDatatype<
    String m_fieldDatatype;
    public String getFieldDatatype() { return m_fieldDatatype; }
    public void setFieldDatatype(String value) { m_fieldDatatype = value; }

    // -----
    // methods
    // -----

    /** */
}
```

```

public ValidValueLine[] findValidValuesForFieldValue()
{
    String text1 = m_adapter.replaceLiteral(ML_APP, "dlfi_code_1");
    String text2 = m_adapter.replaceLiteral(ML_APP, "dlfi_code_2");
    String text3 = m_adapter.replaceLiteral(ML_APP, "dlfi_code_3");
    String text4 = m_adapter.replaceLiteral(ML_APP, "dlfi_code_4");
    String text5 = m_adapter.replaceLiteral(ML_APP, "dlfi_code_5");
    String text6 = m_adapter.replaceLiteral(ML_APP, "dlfi_code_6");
    String text7 = m_adapter.replaceLiteral(ML_APP, "dlfi_code_7");
    String text8 = m_adapter.replaceLiteral(ML_APP, "dlfi_code_8");
    String text9 = m_adapter.replaceLiteral(ML_APP, "dlfi_code_9");
    String text10 = m_adapter.replaceLiteral(ML_APP, "dlfi_code_10");

    if (m_fieldDatatype != null &&
        m_fieldDatatype.equalsIgnoreCase(text1))
    {
        return new ValidValueLine[]
        {
            new ValidValueLine(text2, text3),
            new ValidValueLine(text4, text5)
        };
    }
    if (m_fieldDatatype != null &&
        m_fieldDatatype.equalsIgnoreCase(text6))
    {
        return new ValidValueLine[]
        {
            new ValidValueLine(text2, text7),
            new ValidValueLine(text8, text9)
        };
    }
    throw new Error(text10);
}
}

```

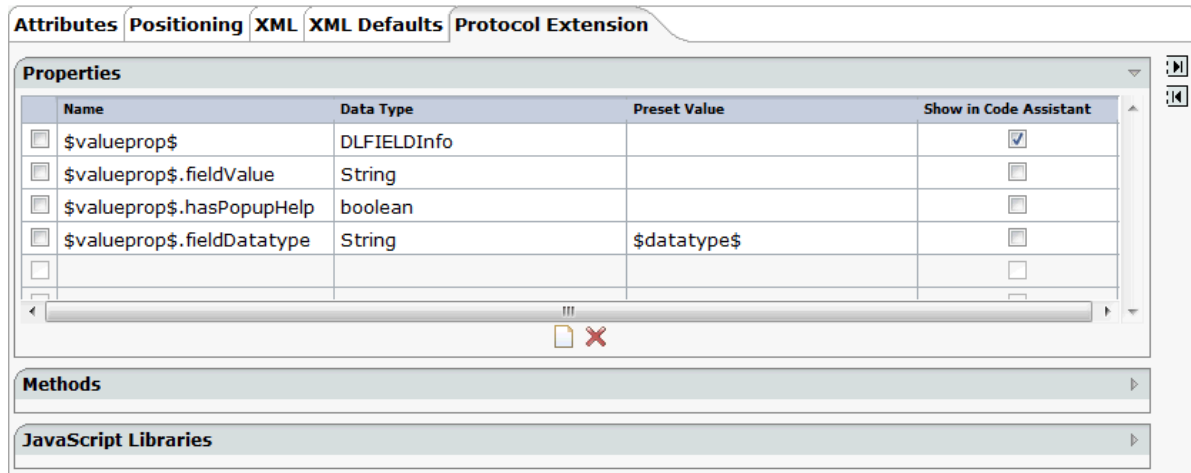

- 6 Select the **XML** tab and change the existing macro as follows:

```

<coltable0 width="$width$" >
  <tr>
    <label name="$name$" width="100%" asplaintext="true">
    </label>
  </tr>
  <tr>
    <field valueprop="$valueprop$.fieldValue" popupmethod="openIdValueCombo" ←
    popupprop="$valueprop$.hasPopupHelp" width="100%">
    </field>
  </tr>
</coltable0>

```

- 7 Add the used properties to the **Protocol Extension** tab so that it looks as follows.

The properties `$valueprop$`, `$valueprop$.fieldValue` and `$valueprop$.hasPopupHelp` will be included in the access path of the layout.

You can specify whether a property is to be shown within the Code Assistant of the Layout Painter. Select only the properties that must be provided by the adapter itself (in this example, this is property `$valueprop$`). Do not select the properties that are provided by the control representative. This class is written once and used multiple times within your adapters.

The property `$valueprop$.fieldDatatype` is used to pass the value of the attribute `datatype` from the control to the class `DLFIELDInfo`. The value is set once when the page is loaded. With this, the `DLFIELDInfo` class determines whether pop-up help is available and computes the list of valid values for the pop-up help.

- 8 Save your changes.
- 9 Have a look at the generated XML file (*editor_test.xml*). It should now look as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<!--
Dynamic extension of editor.xml file.
-->

<controllibrary>
  <editor>

  <!--
*****
* DATATYPES
*****
-->

  <!-- TEST:DLFDATATYPE -->
  <datatype name="test:dlfdatatype">
    <value id="default" name="Default Value."/>
```

```

    <value id="language" name="DLFIELD with Language Code."/>
    <value id="country" name="DLFIELD with Country Code."/>
</datatype>

<!--
*****
* TAGs
*****
-->

<!-- TEST:DLFIELD -->
<tag name="test:dlfield">
  <attribute name="name"/>
  <attribute name="width" datatype="width"/>
  <attribute name="valueprop" datatype="property"/>
  <attribute name="datatype" datatype="test:dlfdatatype"/>
  <taginstance>
    <coltable0 width="$width$">
      <tr>
        <label name="$name$" width="100%" asplaintext="true">
        </label>
      </tr>
      <tr>
        <field valueprop="$valueprop$.fieldValue" popupmethod="openIdValueCombo" ←
popuppprop="$valueprop$.hasPopupHelp" width="100%">
        </field>
      </tr>
    </coltable0>
  </taginstance>
  <protocolitem>
    <addproperty name="$valueprop$" datatype="DLFIELDInfo" ←
useincodgenerator="true"/>
    <addproperty name="$valueprop$.fieldValue" datatype="String"/>
    <addproperty name="$valueprop$.hasPopupHelp" datatype="boolean"/>
    <addproperty name="$valueprop$.fieldDatatype" datatype="String" ←
presetvalue="$datatype$"/>
  </protocolitem>
</tag>
<tagsubnodeextension control="itr" newsubnode="test:dlfield"/>
<tagsubnodeextension control="tr" newsubnode="test:dlfield"/>

<taggroupsubnodeextension group="MyControls" newsubnode="test:dlfield"/>

</editor>
</controllibrary>

```

The control is now ready for use. The Layout Painter will offer the control for the containers ITR and TR.

Additional Information

If you are working with NaturalONE, see the macro control examples of the **njxdemos**.

If you have also installed the standalone version of Natural for Ajax, you can find the sources of the above described DLFIELD example in the **cisdemos**:

- `<your-webapplication>/cisdemos/xml/35_dlfield.xml`
- `<your-webapplication>/cisdemos/src/com/softwareag/cis/test35/DLFIELDAdapter.java`
- `<your-webapplication>/cisdemos/src/com/softwareag/cis/test35/DLFIELDInfo.java`

V

■ 14 Tracing	141
■ 15 Monitoring	149
■ 16 Server Logs Viewer	153

14 Tracing

- About the Tracing Tools 142
- Recording a Performance Trace 142
- Executing a Performance Trace 145

About the Tracing Tools

The tracing tools can be used to test the performance of a web application. First, you record a performance trace (that is, your interaction with the server), and then you execute the recorded performance trace in order to determine the amount of time that is required for processing the server requests.

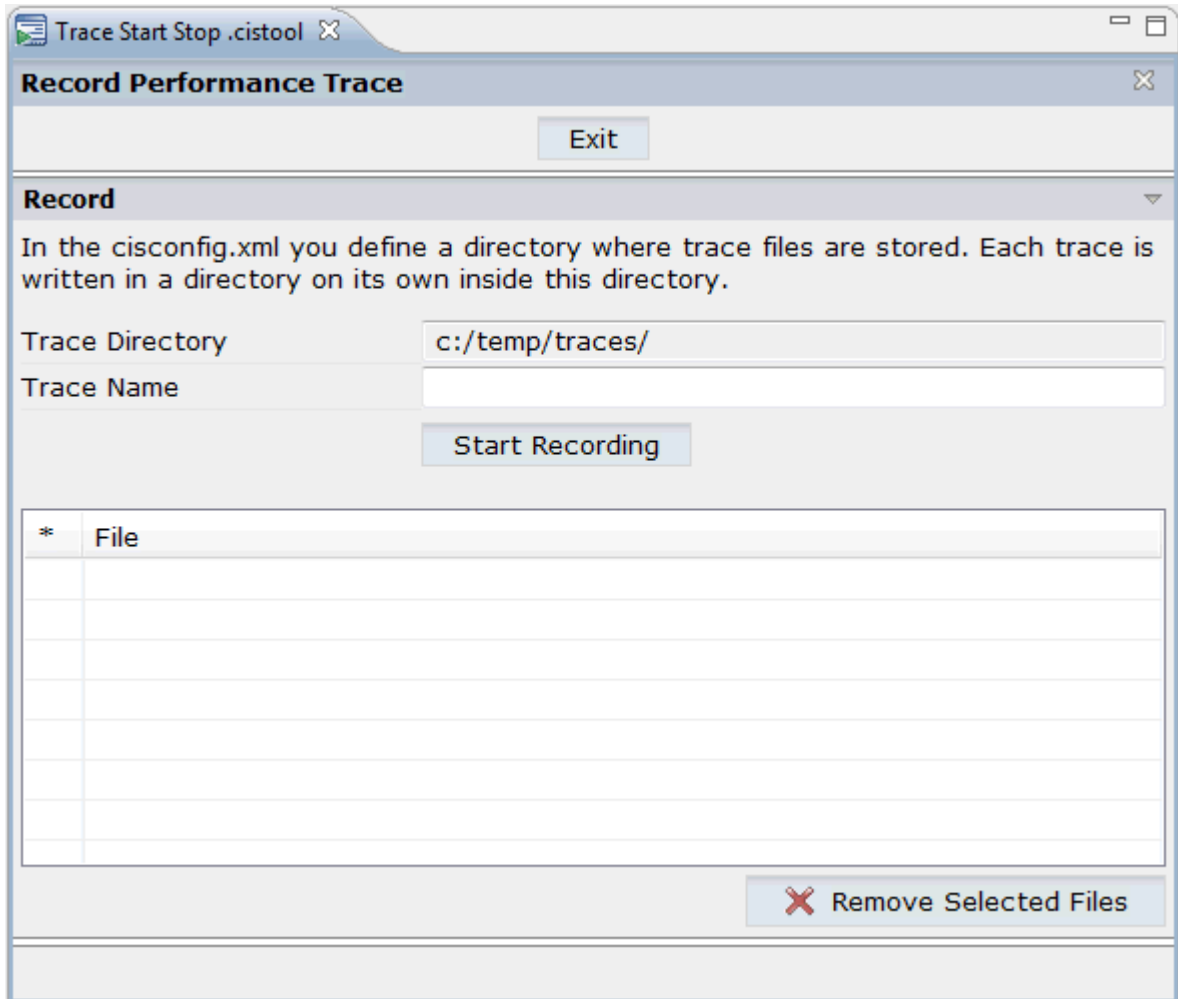

Recording a Performance Trace

Performance traces are recorded using the **Trace Start/Stop** command.

▶ To record a performance trace

- 1 In the **Navigator** view, select the project for which you want to record a performance trace.
- 2 Invoke the context menu and from the **Ajax Developer** menu, choose **Trace Start/Stop**.

The following editor appears.

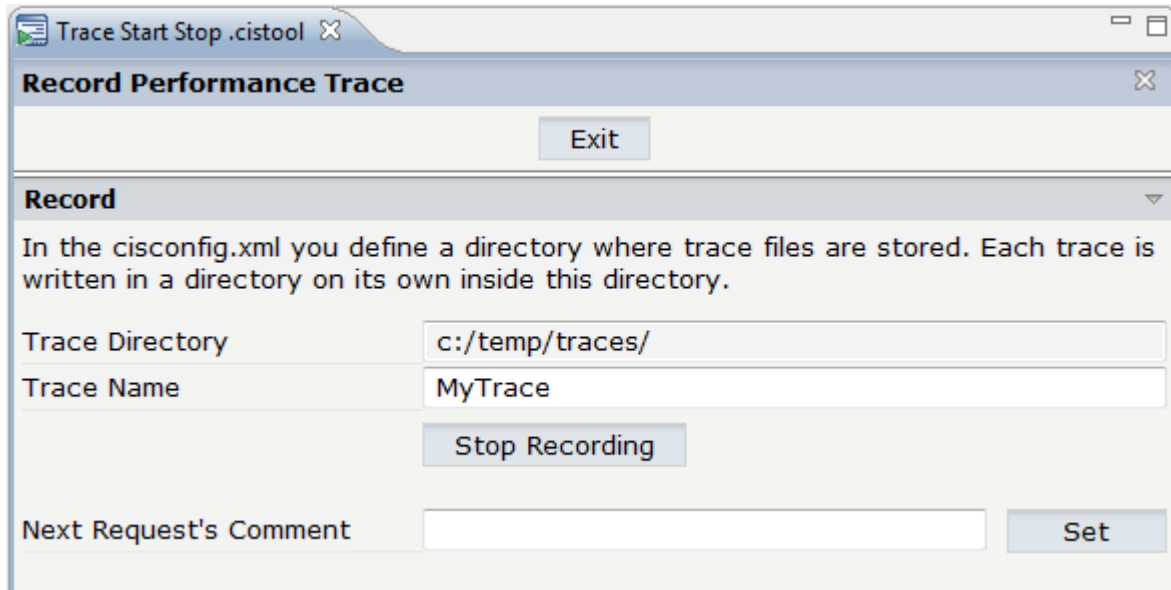

The **Trace Directory** text box indicates the directory in which the traces will be stored. The name of this directory is defined in the file *cisconfig.xml*.

Each trace is written into a separate subdirectory of the trace directory. The name of the subdirectory is determined by your specification in the **Trace Name** text box.

 **Note:** Make sure that the trace directory is available at the specified location. Otherwise, traces will not be written.

- 3 Enter the name of a subdirectory in the **Trace Name** text box.
- 4 Choose the **Start Recording** button.

Additional information is now shown in the editor.

- 5 In the **Next Request's Comment** text box, enter a comment name for the current trace.

Using comment names, you can subdivide the trace into several sections. The comment name is used in the names of the files that are created for your server requests (see below).

- 6 Choose the **Set** button.

The comment name that you specified is shown below the **Next Request's Comment** text box.

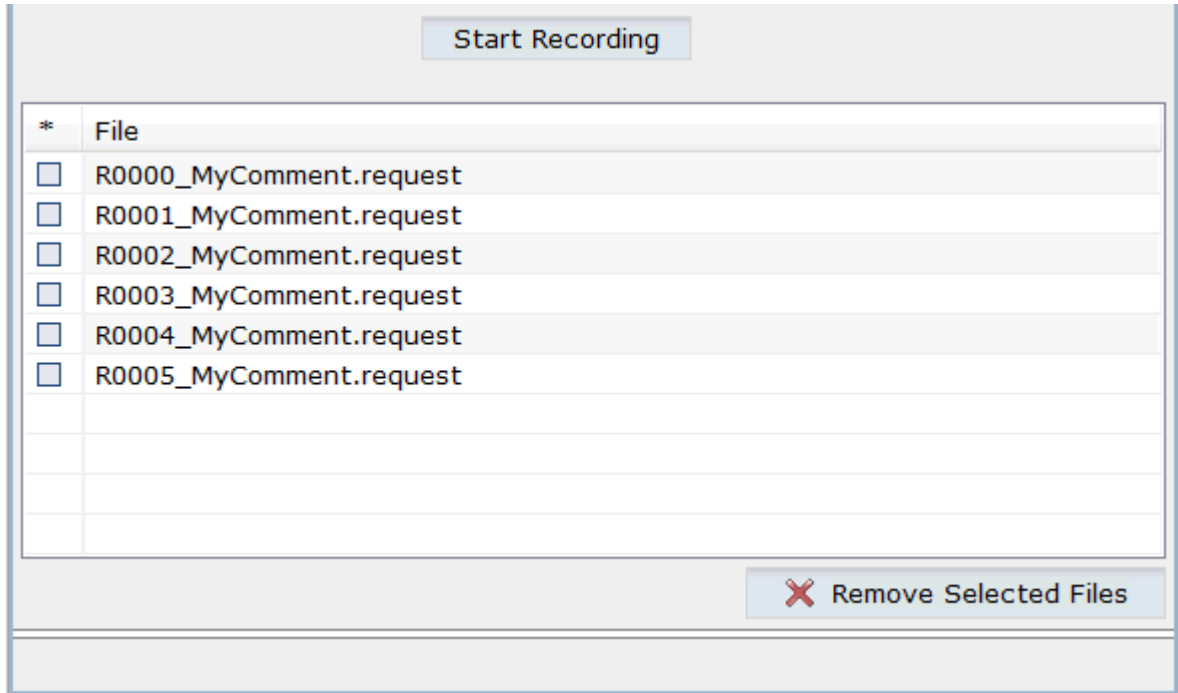

- 7 Initiate an interaction with the server.

For example, open the Layout Painter, and then return to the trace editor.

All requests (interactions with the server) that you initiate are recorded.

- 8 Choose the **Stop Recording** button.

The files that have been created for your requests are shown in the dialog. The comment name that you specified is part of the file name.

If you want to remove one or more files from the list, select the file(s) and choose the **Remove Selected Files** button.

You can add further requests to this trace by repeating the above steps.

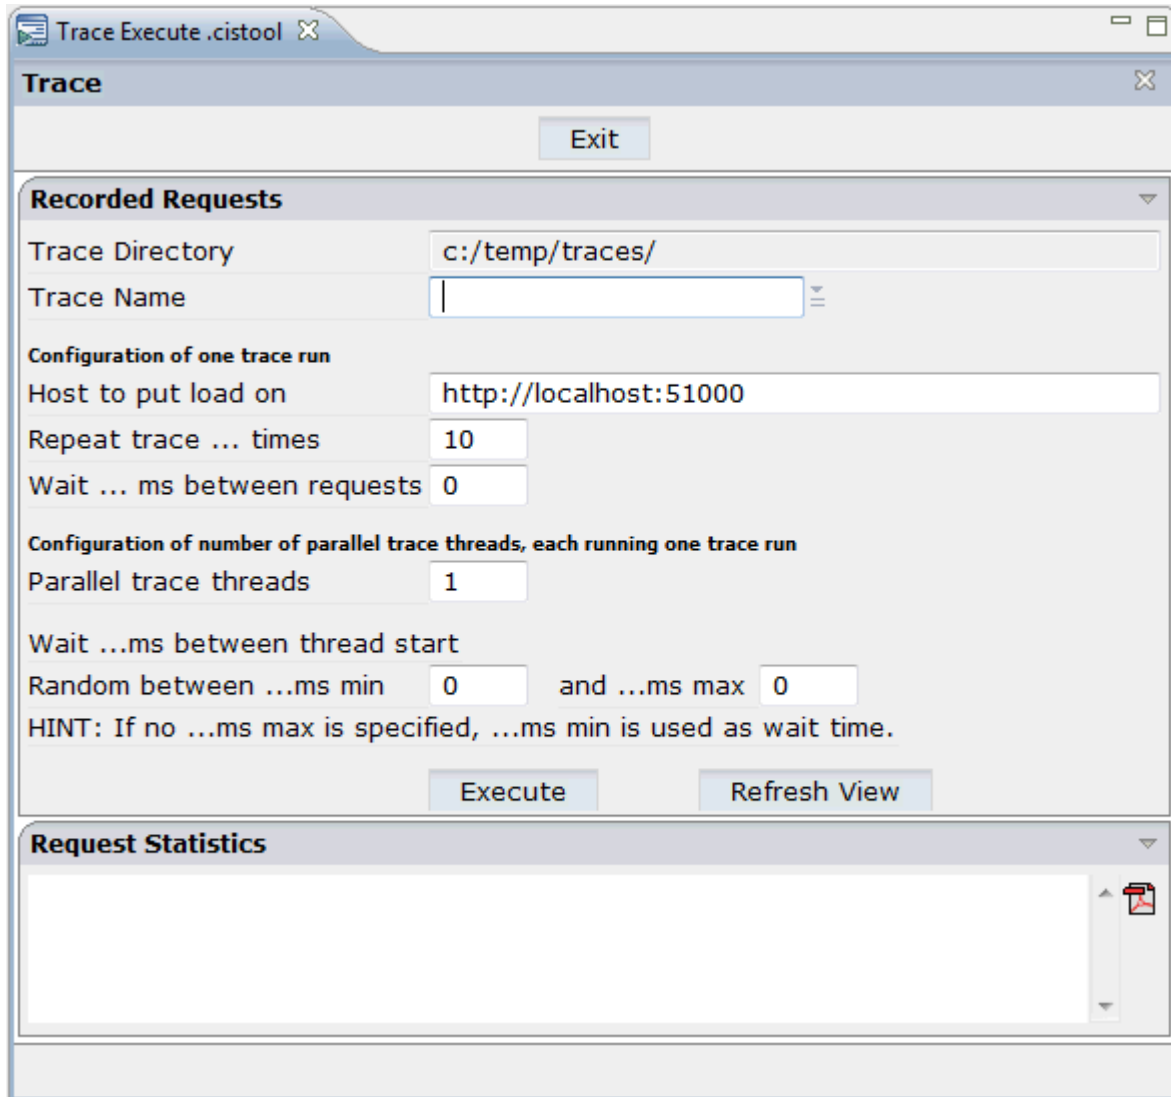

Executing a Performance Trace

Recorded performance traces are executed using the **Trace Execute** command.

▶ To execute a performance trace

- 1 In the **Navigator** view, select the project for which you want to execute a performance trace.
- 2 Invoke the context menu and from the **Ajax Developer** menu, choose **Trace Execute**.

The following editor appears.

The **Trace Directory** text box indicates the directory in which the tool looks for the recorded traces.

3 Specify the following information:

Trace Name

Select the name of the subdirectory which contains the recorded traces for your server requests.

Host to put load on

Enter the URL of the host on which you want to execute the trace.

Repeat trace ... times

Enter the number of times that the trace is to be repeated.

For all defined repetitions, the average process time (in milliseconds) will be shown in the request statistics (see below). The more repetitions you define, the more conclusive is the resulting average value.

Wait ... ms between requests

Enter the waiting time between the requests in milliseconds.

Parallel trace threads

Enter the number of parallel trace threads. This simulates the number of users that access the web application at the same time.

Wait ... ms between thread start

Often you do not want all threads to be started at the same time because this does not match the real scenario in a production environment. Instead, you would like to start the threads one after another with some waiting time in between. For the waiting time, you can specify a fixed value or a range of values. If you specify a range of values, a random number which is in the specified range is used for the waiting time.

- 4 Choose the **Execute** button.
- 5 Choose the **Refresh View** button to display the request statistics at the bottom of the dialog.

Information on the requests is now shown in the **Request Statistics** section:

Request Statistics						
Trace Threads						
Working			Finished			
1			0			
Overview						
Request	Calls	OK	ERR	Duration	Min	Max
Trace file name: c:/temp/traces/MyTrace/traceresults_20130328115110743.csv						

The first small table indicates the current number of unfinished and finished trace threads.

The second table provides a statistical evaluation of the executed requests. The following information is provided for each request: the number of calls, the number of successful executions, the number of errors, the average process time for all calls (duration), the minimum process time for a call, and the maximum process time for a call. The times are given in milliseconds.

In the case of an error, an additional table is shown which provides details on the error.

You can choose the following button in the **Request Statistics** section to display the request statistics in PDF:

The trace result is stored in a CSV file. The path to this file is indicated at the bottom of the dialog.

15 Monitoring

▪ About the Monitoring Tool	150
▪ Invoking the Monitoring Tool	150
▪ Memory	151
▪ Active Sessions	151
▪ System Management	152

About the Monitoring Tool

The monitoring tool is used to monitor the sessions that are currently running in the local web container environment.

To monitor the sessions of an application that has been deployed to another web container, you use the monitoring tool directly in the deployed application. A link to that monitoring tool is available on the default index page that is packaged along with the application (see also *Content of a Natural for Ajax Web Application*, which is part of the NaturalONE documentation).

Sessions which are no longer required can be deleted and memory can thus be freed. For more information on sessions, see *Details on Session Management* in *Special Development Topics*.

Invoking the Monitoring Tool

When you invoke the monitoring tool, the following editor appears.

Monitoring.cistool

Refresh

Memory

Used memory: 30847864
Process memory: 247595008

Active Sessions

* <input type="checkbox"/>	Client	Session	Logged on for (ms)	Last activity since (ms)	Processing	# Processes
<input type="checkbox"/>	<unkown>	SWT_136...	8	7	true	1
<input type="checkbox"/>						
<input type="checkbox"/>						
<input type="checkbox"/>						
<input type="checkbox"/>						
<input type="checkbox"/>						
<input type="checkbox"/>						
<input type="checkbox"/>						
<input type="checkbox"/>						

System Management

Class Loader:

Text Buffer:

Server Log File: Normal Mode Debug Mode

The editor is subdivided into several areas:

- **Memory**
- **Active Sessions**
- **System Management**

Using the **Refresh** button at the very top of the editor, you can reload the information in the editor and thus show the most recent information.

▶ **To invoke the monitoring tool**

- 1 In the **Navigator** view, select the project for which you want to invoke the monitoring tool.
- 2 Invoke the context menu and from the **Ajax Developer** menu, choose **Monitoring**.

Memory

The top of the editor provides the following information:

Option	Description
Used memory	This text box indicates the currently used memory.
Process memory	This text box indicates the available memory.
Collect garbage	When you choose this command button, memory which is no longer used on the server is set free.

Active Sessions

The middle of the editor provides a list with all sessions which are currently active.

The monitoring process itself is also considered as a session. When no other sessions are active, the monitoring process is the only session that is listed in the editor.

The following command buttons are available:

Command Button	Description
Remove	When you choose this command button, the selected sessions are removed from the list of active sessions.
Remove temporary sessions	When you choose this command button, all sessions (except the monitoring session itself) are removed from the list of active sessions.

System Management

The bottom of the editor provides the following information:

Option	Description
Class Loader	<p>When you choose the Use latest Version of Applications for new Sessions command button, a new class loader instance is generated. The most recent versions of your applications are then loaded. For example, when an adapter class has been modified, the modified class is loaded and any changes are immediately in effect.</p> <p>See also <i>Class Loader Concepts</i> in <i>Appendices</i>.</p>
Text Buffer	<p>When you choose the Refresh Text Buffer command button, the most recent versions of your language files are loaded and any changes are immediately in effect.</p> <p>When you choose the Refresh Layout Repository Buffer command button, the most recent versions of your layouts are loaded and any changes are immediately in effect.</p>
Server Log File	<p>The server log file contains a protocol of all interactions with the server. You can select the option button for the required log mode: Normal Mode or Debug Mode. In debug mode, the log contains more detailed information.</p> <p>When you choose the Open Today's Log File command button, a dialog appears showing the content of the log file.</p>

16 Server Logs Viewer

- About the Server Logs Viewer 154
- Preconfigured Server Logs 154
- Advanced Usage 156

About the Server Logs Viewer

The server logs viewer is preconfigured to view the server logs of the user interface components. All user interface components of a project which has been enabled for Ajax Developer share the same server log. This is described under [Preconfigured Server Logs](#).

In addition, the server logs viewer can be used to view all kind of other log files. This is described under [Advanced Usage](#).

Preconfigured Server Logs

The **Server Logs Viewer** view is automatically opened when a project is enabled for Ajax Developer. A predefined log viewer is automatically available for this project. To display this predefined log viewer in the **Server Logs Viewer** view, you have to create an entry for it, as described below.

▶ To create an entry for a predefined log viewer

- 1 In the **Navigator** view or in the **Natural Navigator** view, select the project which has been enabled for Ajax Developer.
- 2 Go to the **Server Logs Viewer** view.

If this view is not active, you can open it as described under [Opening the Server Logs View](#).

- 3 Choose the following icon in the local toolbar:

- 4 In the resulting dialog box, open the **Select a predefined log viewer** drop-down list box and select the predefined log viewer. The name of the predefined log viewer is `<project-name>/Ajax Developer Server Log`.

When you select the predefined log viewer, Ajax Developer automatically sets the correct log location for the project. A predefined filter is used. If you want, you can customize the filter settings. See [Creating a Log Viewer](#) for further information.

Create new Log Viewer

LogViewer Details

If the log viewer that you want to add is already present in the "predefined log viewer" list then select it to use its settings, else you must enter all the details of the LogViewer manually.

Select a predefined log viewer: **MyFirstProject/Ajax Developer Server Log**

Description
Ajax Developer Server Log for the selected project.

Log viewer details

Log file to view is fixed:

Name of the log file varies:

Select log file directory: **C:\Users\kol\workspace83\naturalone\apache-tomcat\w**

Log file name pattern: **serverLog_\${yyyy}\${mm}\${dd}.log** Add pattern: **\${yyyy}**

Name of the view: **MyFirstProject/Ajax Developer Server L**

Refresh interval (in seconds): **5**

Log viewer options

Show entire file when first opened for viewing

No, show only specified number of lines when first opened for viewing

Number of lines to show **10**

Line filters

If line CONTAINS "Request consumed" THEN change its style.

- 5 Choose the **Finish** button.

An entry for the log viewer is now shown in the **Server Logs Viewer** view. When you double-click this entry, the log file is opened. See also [Opening a Log Viewer](#).

Advanced Usage

The server logs viewer can also be used to view other log files, for example, the server logs of the Tomcat server. The server logs viewer can be used to view single or multiple log files. A log file records activities and operations that occurred on a server/computer, maintaining an operational history of these activities. A log file is identified by its *.log* extension.

A log viewer allows the user to:

- Specify refresh intervals.
- Specify the number of lines to be displayed from a file.
- Customize the way to view files by specifying filter conditions.
- Save the log files added in the viewer so that the user is able access them easily the next time.
- Provide extension points so as to enable other Eclipse plug-ins to contribute their log files for viewing.

The following topics are covered below:

- [Opening the Server Logs Viewer](#)
- [Creating a Log Viewer](#)
- [Editing a Log Viewer](#)
- [Opening a Log Viewer](#)

Creating a Log Viewer

You can create an entry for a new log viewer by using the settings of an existing log viewer (for example, of the predefined log viewer) and then modifying the settings according to your requirements.

▶ To create an entry for a new log viewer

- 1 Go to the **Server Logs Viewer** view.
- 2 Choose the following icon in the local toolbar:

The following dialog box appears.

Create new Log Viewer

LogViewer Details

If the log viewer that you want to add is already present in the "predefined log viewer" list then select it to use its settings, else you must enter all the details of the LogViewer manually.

Select a predefined log viewer:

Description

Log viewer details

Log file to view is fixed:

Name of the log file varies:

Select log file directory:

Log file name pattern: Add pattern:

Name of the view:

Refresh interval (in seconds):

Log viewer options

Show entire file when first opened for viewing

No, show only specified number of lines when first opened for viewing

Number of lines to show

Line filters

- Specify the following information:

Select a predefined log viewer

To create a new log viewer, keep the default value **New Log Viewer**.

If you want to use an existing log viewer as the basis for the new log viewer, select it from this drop-down list box. The description for the selected log viewer is then shown in the **Description** text box.

Log file to view is fixed

Select this option if the log file that must be viewed is fixed, that is, if its name does not change. The log viewer will view/read this file every time. Use the **Browse** button to select the log file.

Name of the log file varies

Select this option if the name of the log file changes on some criteria. For example, if the name of the log file contains a timestamp which is changed daily, the name of the log file also varies daily. Specify the following information in this case:

Option	Description
Select log file directory	Use the Browse button to select the directory containing the log files. For example, <code><myworkspace>\.naturalone\apache-tomcat\logs</code> for the log files of your local Apache Tomcat.
Log file name pattern	Specify the date pattern of your log files. For example, <code>catalina.\${yyyy}-\${mm}-\${dd}.log</code> for the log files of your local Apache Tomcat. Note: Ensure that you know the log file naming conventions used in your application before specifying this information.
Add pattern	Select the date format from the available options in the drop-down list box. Choose the button containing the plus sign to add each pattern to the Log file name pattern text box.

Name of the view

Enter a name to identify this viewer.

Refresh interval (in seconds)

The log viewer refreshes the view as per the interval you specify here.

Log viewer options

Choose the option to either view the entire log file or only a specified number lines when first opened for viewing. If you select the latter option, you need to specify the number of lines to be displayed.

Line filters

Choose the **Add Filter** button if you wish to add filters to the log files you view. Using these features, you can filter lines based on some conditions such as skipping the entire line or changing the display style in the view.

You add the line filters in the resulting dialog box. For example, to view a line highlighted in black and the font color as green, specify the following:

1. From the **If line** drop-down list box, select **Contains text** and enter "Info" in the text box.
2. Select the **Change the style of the line** option button.
3. Choose the **Foreground color** button and select the color green.

4. Choose the **Background color** button and select the color black.
5. Choose the **OK** button.

The following information is then shown:

```
If line CONTAINS "Info" THEN change its style.
```

To remove the selected line filter or all line filters, choose either the **Remove** or **Remove All** button.

- 4 Choose the **Finish** button.

Editing a Log Viewer

When you edit a log viewer, the same information is shown as when adding a new log viewer.

▶ To edit a log viewer

- 1 In the **Server Logs Viewer** view, select the log viewer that you want to edit.
- 2 Invoke the context menu and choose **Edit Log Viewer**.

Or:

Choose the following icon in the local toolbar:

A dialog appears.

- 3 Modify all required information as described in [Creating a Log Viewer](#).

In edit mode, it is not possible to change the log file to be viewed. The corresponding options are disabled.

- 4 Choose the **OK** button.

Opening a Log Viewer

When you open a log viewer, it is shown on a separate tab of the **Server Logs Viewer** view. It shows the contents of the defined log file.

▶ To open one or more log viewers

- 1 In the **Server Logs Viewer** view, select the log viewers that you want to open.
- 2 Invoke the context menu and choose **Open Log Viewer(s)**.

Or:

Choose the following icon in the local toolbar:

Or:

If you want to to open a single log viewer, you can simply double-click it.

A separate tab for each selected log viewer is provided in the **Server Logs Viewer** view.

If you want to remove such a tab, choose the close button that is shown next to the tab name.

Removing a Log Viewer

When you remove a log viewer, it is no longer shown in the **Server Logs Viewer** view.

▶ To remove one or more log viewers

- 1 In the **Server Logs Viewer** view, select the log viewers that you want to remove.
- 2 Invoke the context menu and choose **Remove Log Viewer(s)**.

Or:

Choose the following icon in the local toolbar:

A dialog appears, asking whether you really want to remove the selected log viewers.

- 3 Choose the **OK** button.
