 Using Environment Variables under z/VSE 	

This chapter gives an overview of environment variables in EntireX and how they are used.

Table of Environment Variables

The table below provides an overview of environment variables used on the various platforms supported by EntireX.

			Platfo	rm		Opt/			
Environment Variable	z/OS	Win	UNIX	z/VSE	z/VM	Req	Description	More Information	
SAG			x			R	Root directory for all Software AG infrastructure products (e.g. System Management Hub, Software AG Common Platform).		
EXXDIR			х			R	Top level directory for EntireX.		
EXXVERS			x			R	Version level directory of the EntireX. Deprecated. Kept for reasons of compatibility with earlier versions.		
PATH			x			R	System variable. Additional program directories required by EntireX are added to this variable by the EntireX environment script. Not required by EntireX Mini Runtime.	See Shell Environment Settings under Post-installation Steps under UNIX.	
LD_LIBRARY_PATH			x			R	System variable. Additional shared library directories required by EntireX are added to this variable by the EntireX environment script.	See Shell Environment Settings under Post-installation Steps under UNIX.	
SHLIB_PATH			x			R	Same as LD_LIBRARY_PATH on HP-UX.	See Shell Environment Settings under Post-installation Steps under UNIX.	
LIBPATH			x			R	Same as LD_LIBRARY_PATH on AIX.	See Shell Environment Settings under	

Platfo		Platfo	form					
Environment Variable	z/OS	Win	UNIX	z/VSE	z/VM	Opt/ Req	Description	More Information
								Post-installation Steps under UNIX.
CLASSPATH		x	x			R	System variable. Additional JAR file path entries required by EntireX are added to this variable by the EntireX environment script (UNIX) or during installation (Windows).	
ARGDIR			x			R	Home directory of the System Management Hub	See System Management Hub for EntireX.
ARGVERS			x			R	Version of the System Management Hub	
ETB_ATTR		x	x			0	Value of Broker attribute file. Set automatically by the Broker startup shell script.	See <i>Broker Attributes</i> in the platform-independent administration documentation.
ETB_LOG		x	x			0	Accounting file.	See <i>Accounting in EntireX</i> <i>Broker</i> in the general administration documentation.
ETB_NONACT NONACT	x	x	x	x		0	Limits the TCP/IP connection lifetime.	Stub-to-broker connection non-activity time in seconds. If not 0, connections with a non-activity time greater than ETB_NONACT will be closed. See <i>Limiting the</i> <i>TCP/IP Connection Lifetime</i> in the platform-specific <i>Stub</i> <i>Administration</i> sections of the EntireX documentation.
ETB_SOCKETPOOL	x	x	x			0	Values: ON (default) or OFF to establish an affinity between threads and TCP/IP connections in a DVIPA environment.	See Support of Clustering in a High Availability Scenario under Administration of Broker Stubs in the platform-specific administration documentation.
ETB_STUBLOG STUBLOG	x	x	x	x	x	0	Trace level for the EntireX Broker API.	See Application Stublog File in the UNIX administration documentation Tracing for Broker Stubs under z/OS z/VM.

			Platfo	rm		Opt/		
Environment Variable	z/OS	Win	UNIX	z/VSE	z/VM		Description	More Information
ETB_STUBLOGPATH		x	x			0	Under UNIX and Windows, the directory where the log file is created if ETB_STUBLOG is used.	
ETB_TIMEOUT TIMEOUT	x	x	x	x	x	0	Stub transport timeout.	See Setting the Timeout for the Transport Method in the platform-specific broker stub administration documentation.
ERX_TRACELEVEL		x	х			0	Sets the trace level for EntireX RPC Runtime.	Tracing for various EntireX components such as DCOM Wrapper, .NET Wrapper and C Wrapper. See <i>Tracing</i> <i>webMethods EntireX</i> in the platform-specific administration documentation.
ETB_TRANSPORT TRANSPORT	x	x	x	x		0	Sets the default transport method for Broker stubs.	
ADALNK		x	x			0	The Adabas module that is needed by the Broker kernel to access the Adabas persistent store.	See <i>Managing the Broker</i> <i>Persistent Store</i> in the platform-specific administration documentation.
ETBLNK			х			R	Identifies the absolute path to the broker stubs library if EntireX Broker has been installed.	See Broker Stubs under Post-installation Steps under UNIX.
ERX_TRACEFILE		x	x			0	Sets the name of the trace file for EntireX RPC Runtime.	Tracing for various EntireX components such as DCOM Wrapper, .NET Wrapper and C Wrapper. See <i>Tracing</i> <i>webMethods EntireX</i> in the platform-specific administration documentation.
ERX_ETBAPIVERS		x	х			0	Determines the Broker API version to use.	EntireX components such as DCOM Wrapper, .NET Wrapper and C Wrapper and the EntireX Broker are

	Platform			Opt/				
Environment Variable	z/OS	Win	UNIX	z/VSE	z/VM		Description	More Information
								able to detect automatically the best API version to use (if no environment variable is defined or the value 0 is assigned). However, for backward compatibility to EntireX Broker, it might be necessary to set a preferred API Version for the Broker.
ERX_CODEPAGE		x	x			0	Sets the locale string to be used for internationalization with the EntireX RPC Runtime.	various EntireX components
NA2_BKDBGS		x	x			0	Security exit debug level. Used for protecting the Broker kernel on UNIX and Windows to leverage the local security system.	
NA2_BKDBGF		x	x			0	Security exit debug file. Used for protecting the Broker kernel on UNIX and Windows to leverage the local security system.	See Setting up EntireX Security for Broker Kernel in the UNIX and Windows post-installation documentation.
NA2_BKDIAG		x	x			0	Security exit diagnostics. Use only if requested by Software AG support.	
NA2_BKPRIV		x	x		x	0	Security exit setting.	See Setting up EntireX Security for Broker Kernel in the UNIX and Windows post-installation documentation; Step 4: Rename SECUEXI0 to SECUEXIT for Security (Optional) in the z/VM installation documentation.
REGFILE			х			R	RGS repository for Software AG Base Technology components under UNIX.	

Using Environment Variables under z/OS

Under CICS, Batch and IMS, use the SAGTOKEN Utility to set and delete environment variables. See *SAGTOKEN Utility* under *Administering Broker Stubs* in the z/OS administration documentation.

In Com-plete, use the EXAENV environment store to set and delete environment variables. See *EX*-*AENV Environment Store* under *Administering Broker Stubs*.

Using Environment Variables under UNIX

The following table shows how to use environment variables with the C, Bourne and Korn shells. For other shells, see your UNIX documentation.

C Shell

Action	Syntax	Example
Set environment variable	setenv <i>variable value</i>	setenv ERX_TRACELEVEL ADVANCED
Delete environment variable	unsetenv <i>variable</i>	unsetenv ERX_TRACELEVEL

Bourne and Korn Shells

Action	Syntax	Example
		ERX_TRACELEVEL=ADVANCED export ERX_TRACELEVEL
Delete environment variable	unset <i>variable</i>	unset ERX_TRACELEVEL

Using Environment Variables under Windows

The following table shows how to use environment variables under Windows:

Action	Syntax	Examples
Set environment variable		SET ERX_TRACELEVEL=ADVANCED SET ETB_STUBLOG=NONE
Delete environment variable	SET variable =	SET ERX_TRACELEVEL=

Using Environment Variables under BS2000/OSD (Batch, Dialog)

Environment variables are emulated with SDF variables or, failing that, with job variables.

Replace all underscores in the variable names by hyphens. For example, variable ETB_STUBLOG is called ETB-STUBLOG under BS2000/OSD.

The following table shows how to use job variables under BS2000/OSD:

Action	Syntax		Example	
Set environment variable	/CATJV	variable	/CATJV	ETB-STUBLOG
	/SETJV	variable,C'value'	/SETJV	ETB-STUBLOG,C'1'
Delete environment variable	/ERAJV	variable	/ERAJV	ETB-STUBLOG

Using Environment Variables under z/VSE

Action	Syntax	Examples
Set environment variable	//SETPARM variable = value	//SETPARM STUBLOG=2
Delete environment variable	Remove SETPARM statement	/* /SETPARM STUBLOG=2

2 Directories as Used in EntireX

Application Data Directory	. 11
Broker Directory	
Broker User Exit Directory	. 11
Application Data Directory	. 11
Trace Directory	11
User's Home Directory	12
Working Directory	. 12
EntireX Directory etc	12

Application Data Directory

Windows

Under Windows, the application data directory is the folder that serves as a common repository for application-specific data.

Example: C:\Documents and Settings\username\Application Data

Broker Directory

UNIX

This directory is a subdirectory of the EntireX main directory */opt/softwareag/EntireX/con-fig/etb/<brokerid>*.

Example: /opt/softwareag/EntireX/config/etb/ETB001

Windows

This directory is a subfolder of the EntireX *config* directory *<drive>:\SoftwareAG\EntireX\con-fig\etb\
brokerid>*.

Example: <drive>:\SoftwareAG\EntireX\config\etb\ETB001

Broker User Exit Directory

UNIX

This directory is a subdirectory of the EntireX main directory /opt/softwareag/EntireX/security_exit.

Windows

This directory is a subfolder of the EntireX main directory, for example: *C*:*SoftwareAG**EntireX**security_exit*.

Application Data Directory

Windows

The local application data directory is a folder that serves as a common repository for (non-roaming) application-specific data.

Example: C:\Documents and Settings\username\Application Data

Trace Directory

Windows

Traces are written into the .. *My Documents* *Software AG* *EntireX* folder. The location of the folder *My Documents* can be specified by the user. By default it is a subdirectory of the user's *Profile* folder referenced by the %USERPROFILE% environment variable.

Example: C:\Documents And Settings\username\My Documents\Software AG\EntireX

User's Home Directory

Windows

This folder is also known as the *My Documents* folder. The location of the folder *My Documents* can be specified by the user. By default it is a subdirectory of the *Profile* folder referenced by the %USERPROFILE% environment variable.

Example: C:\Documents And Settings\username\My Documents

Working Directory

Windows

This is the directory your application is running in.

Example: *C*:*Temp*

EntireX Directory etc

UNIX

This directory is a subdirectory of the EntireX main directory /opt/softwareag/EntireX/etc.

Windows

This directory is a subfolder of the EntireX main directory *<drive>:\SoftwareAG\EntireX\etc.*

Example: C:\<drive>:\SoftwareAG\EntireX\etc

Broker Resource Allocation

General Considerations	
Specifying Global Resources	
Restricting the Resources of Particular Services	
 Specifying Attributes for Privileged Services 	
Maximum Units of Work	
Calculating Resources Automatically	
Dynamic Memory Management	
Dynamic Worker Management	
Storage Report	
Maximum TCP/IP Connections per Communicator	

The EntireX Broker is a multithreaded application and communicates among multiple tasks in memory pools. If you do not need to restrict the memory expansion of EntireX Broker, we strongly recommend you enable the dynamic memory management in order to handle changing workload appropriately. See *Dynamic Memory Management* below. If dynamic memory management is disabled, non-expandable memory is allocated during startup to store all internal control blocks and the contents of messages.

General Considerations

Resource considerations apply to both the global and service-specific levels:

- Dynamic assignment of global resources to services that need them prevents the return of a "Resource Shortage" code to an application when resources are available globally. It also enables the EntireX Broker to run with fewer total resources, although it does not guarantee the availability of a specific set of resources for a particular service.
- Flow control ensures that individual services do not influence the behavior of other services by accident, error, or simply overload. This means that you can restrict the resource consumption of particular services in order to shield the other services.

In order to satisfy both global and service-specific requirements, the EntireX Broker allows you to allocate resources for each individual service or define global resources which are then allocated dynamically to any service that needs them.

The resources in question are the number of conversations, number of servers, plus units of work and the message storage, separated in a long buffer of 4096 bytes and short buffer of 256 bytes. These resources are typically the bottleneck in a system, especially when you consider that nonconversational communication is treated as the special case of "conversations with a single message only" within the EntireX Broker.

Global resources are defined by the parameters in the Broker section of the attribute file. The number of conversations allocated to each service is defined in the service-specific section of the attribute file. Because the conversations are shared by all servers that provide the service, a larger number of conversations should be allocated to services that are provided by more than one server. The number of conversations required is also affected by the number of clients accessing the service in parallel.

Specifying Global Resources

You can specify a set of global resources with no restrictions on which service allocates the resources:

- Specify the global attributes with the desired values.
- Do not specify any additional restrictions. That is, do not provide values for the following Brokerspecific attributes:

```
LONG - BUFFER - DEFAULT
SHORT - BUFFER - DEFAULT
CONV - DEFAULT
SERVER - DEFAULT
```

Also, do not provide values for the following server-specific attributes:

```
LONG-BUFFER-LIMIT
SERVER-LIMIT
SHORT-BUFFER-LIMIT
CONV-LIMIT
```

Example

The following example defines global resources. If no additional definitions are specified, resources are allocated and assigned to any server that needs them.

```
NUM - CONVERSATION=1000
NUM - LONG - BUFFER=200
NUM - SHORT - BUFFER=2000
NUM - SERVER=100
```

Restricting the Resources of Particular Services

You can restrict resource allocation for particular services in advance:

- Use CONV-LIMIT to limit the resource consumption for a specific service.
- Use CONV-DEFAULT to provide a default limit for services for which CONV-LIMIT is not defined.

Example

In the following example, attributes are used to restrict resource allocation:

```
DEFAULTS=BROKER
NUM-CONVERSATION=1000
CONV-DEFAULT=200
DEFAULTS=SERVICE
CLASS=A, SERVER=A, SERVICE=A, CONV-LIMIT=100
CLASS=B, SERVER=B, SERVICE=B, CONV-LIMIT=UNLIM
CLASS=C, SERVER=C, SERVICE=C
```

- Memory for a total of 1000 conversions is allocated (NUM-CONVERSATION=1000).
- Service A (CLASS A, SERVER A, SERVICE A) is limited to 100 conversation control blocks used simultaneously (CONV-LIMIT=100). The application that wants to start more conversations than specified by the limit policy will receive a "Resource shortage" return code. This return code should result in a retry of the desired operation a little later, when the resource situation may have changed.
- Service B (CLASS B, SERVER B, SERVICE B) is allowed to try to allocate as many resources as necessary, provided the resources are available and not occupied by other services. The number of conversations that may be used by this service is unlimited (CONV-LIMIT=UNLIM).
- Service C (CLASS C,SERVER C,SERVICE C) has no explicit value for the CONV-LIMIT attribute. The number of conversation control blocks that it is allowed to use is therefore limited to the default value which is defined by the CONV-DEFAULT Broker attribute.

The same scheme applies to the allocation of message buffers and servers:

In the following example, long message buffers are allocated using the keywords NUM-LONG-BUFFER, LONG-BUFFER-DEFAULT and LONG-BUFFER-LIMIT:

DEFAULTS=BROKER NUM-LONG-BUFFER=2000 LONG-BUFFER-DEFAULT=250 DEFAULTS=SERVICE CLASS=A, SERVER=A, SERVICE=A, LONG-BUFFER-LIMIT=100 CLASS=B, SERVER=B, SERVICE=B, LONG-BUFFER-LIMIT=UNLIM CLASS=C, SERVER=C, SERVICE=C

In the following example, short message buffers are allocated using the keywords NUM-SHORT-BUFFER, SHORT-BUFFER-DEFAULT and SHORT-BUFFER-LIMIT:

```
DEFAULTS=BROKER
NUM-SHORT-BUFFER=2000
SHORT-BUFFER-DEFAULT=250
DEFAULTS=SERVICE
CLASS=A, SERVER=A, SERVICE=A, SHORT-BUFFER-LIMIT=100
CLASS=B, SERVER=B, SERVICE=B, SHORT-BUFFER-LIMIT=UNLIM
CLASS=C, SERVER=C, SERVICE=C
```

In the following example, servers are allocated using the keywords NUM-SERVER, SERVER-DEFAULT and SERVER-LIMIT:

DEFAULTS=BROKER NUM-SERVER=2000 SERVER-DEFAULT=250 DEFAULTS=SERVICE CLASS=A, SERVER=A, SERVICE=A, SERVER-LIMIT=100 CLASS=B, SERVER=B, SERVICE=B, SERVER-LIMIT=UNLIM CLASS=C, SERVER=C, SERVICE=C

Specifying Attributes for Privileged Services

If privileged services (services with access to unlimited resources) exist, specify UNLIMITED for the attributes CONV-LIMIT, SERVER-LIMIT, LONG-BUFFER-LIMIT and SHORT-BUFFER-LIMIT in the service-specific section of the attribute file.

For example:

DEFAULTS=SERVICE CONV-LIMIT=UNLIM LONG-BUFFER-LIMIT=UNLIM SHORT-BUFFER-LIMIT=UNLIM SERVER-LIMIT=UNLIM

To ensure a resource reservoir for peak load of privileged services, define more resources than would normally be expected by specifying larger numbers for the Broker attributes that control global resources:

NUM-SERVER NUM-CONVERSATION CONV-DEFAULT LONG-BUFFER-DEFAULT SHORT-BUFFER-DEFAULT SERVER-DEFAULT

Maximum Units of Work

The maximum number of units of work (UOWs) that can be active concurrently is specified in the Broker attribute file. The MAX-UOWS attribute can be specified for the Broker globally as well as for individual services. It cannot be calculated automatically. If a service is intended to process UOWs, a MAX-UOWS value must be specified.

If message processing only is to be done, specify MAX-UOWS=0 (zero). The Broker (or the service) will not accept units of work, i.e., it will process only messages that are not part of a UOW. Zero is used as the default value for MAX-UOWS in order to prevent the sending of UOWs to services that are not intended to process them.

Calculating Resources Automatically

To ensure that each service runs without impacting other services, allow the EntireX Broker to calculate resource requirements automatically:

- Ensure that the attributes that define the default total for the Broker and the limit for each service are not set to UNLIM.
- Specify AUTO for the Broker attribute that defines the total number of the resource.
- Specify a suitable value for the Broker attribute that defines the default number of the resource.

The total number required will be calculated from the number defined for each service. The resources that can be calculated this way are Number of Conversations, Number of Servers, Long Message Buffers and Short Message Buffers.

Avoid altering the service-specific definitions at runtime. Doing so could corrupt the conversation consistency. Applications might receive a message such as "NUM-CONVERSATIONS reached" although the addressed service does not serve as many conversations as defined. The same applies to the attributes that define the long and short buffer resources.

Automatic resource calculation has the additional advantage of limiting the amount of memory used to run the EntireX Broker. Over time, you should be able to determine which services need more resources by noting the occurrence of the return code "resource shortage, please retry". You can then increase the resources for these services. To avoid disruption to the user, you could instead allocate a relatively large set of resources initially and then decrease the values using information gained from the Administration Monitor application.

Number of Conversations

To calculate the total number of conversations automatically, ensure that the CONV-DEFAULT Broker attribute and the CONV-LIMIT service-specific attribute are not set to UNLIM anywhere in the attribute

file. Specify NUM-CONVERSATION=AUTO and an appropriate value for the CONV-DEFAULT Broker attribute. The total number of conversations will be calculated using the value specified for each service.

For example:

```
DEFAULTS=BROKER
NUM-CONVERSATION=AUTO
CONV-DEFAULT=200
DEFAULTS=SERVICE
CLASS=A, SERVER=A, SERVICE=A
CLASS=B, SERVER=B, SERVICE=B, CONV-LIMIT=100
CLASS=C, SERVER=C, SERVICE=C
```

- Service A and Service C both need 200 conversations (the default value). Service B needs 100 conversations (CONV-LIMIT=100).
- Because NUM-CONVERSATIONS is defined as AUTO, the broker calculates a total of 500 conversations (200 + 200 + 100).
- NUM-CONVERSATIONS=AUTO allows the number of conversations to be flexible without requiring additional specifications. It also ensures that the broker is started with enough resources to meet all the demands of the individual services.
- AUTO and UNLIM are mutually exclusive. If CONV-DEFAULT or a single CONV-LIMIT is defined as UNLIM, the EntireX Broker cannot determine the number of conversations to use in the calculation, and the EntireX Broker cannot be started.

Number of Servers

To calculate the number of servers automatically, ensure that the SERVER-DEFAULT Broker attribute and the SERVER-LIMIT service-specific attribute are not set to UNLIM anywhere in the attribute file. Specify NUM-SERVER=AUTO and an appropriate value for the SERVER-DEFAULT Broker attribute. The total number of server buffers will be calculated using the value specified for each service.

For example:

```
DEFAULTS=BROKER
NUM-SERVER=AUTO
SERVER-DEFAULT=250
DEFAULTS=SERVICE
CLASS=A, SERVER=A, SERVICE=A, SERVER-LIMIT=100
CLASS=B, SERVER=B, SERVICE=B
CLASS=C, SERVER=C, SERVICE=C
```

Long Message Buffers

To calculate the number of long message buffers automatically, ensure that the LONG-BUFFER-DE-FAULT Broker attribute and the LONG-BUFFER-LIMIT service-specific attribute are not set to UNLIM anywhere in the attribute file. Specify NUM-LONG-BUFFER=AUTO and an appropriate value for the LONG-BUFFER-DEFAULT Broker attribute. The total number of long message buffers will be calculated using the value specified for each service.

For example:

DEFAULTS=BROKER NUM-LONG-BUFFER=AUTO LONG-BUFFER-DEFAULT=250 DEFAULTS=SERVICE CLASS=A, SERVER=A, SERVICE=A, LONG-BUFFER-LIMIT=100 CLASS=B, SERVER=B, SERVICE=B CLASS=C, SERVER=C, SERVICE=C

Short Message Buffers

To calculate the number of short message buffers automatically, ensure that the SHORT-BUFFER-DEFAULT Broker attribute and the SHORT-BUFFER-LIMIT service-specific attribute are not set to UNLIM anywhere in the attribute file. Specify NUM-SHORT-BUFFER=AUT0 and an appropriate value for the SHORT-BUFFER-DEFAULT Broker attribute. The total number of short message buffers will be calculated using the value specified for each service.

For example:

```
DEFAULTS=BROKER
NUM-SHORT-BUFFER=AUTO
SHORT-BUFFER-DEFAULT=250
DEFAULTS=SERVICE
CLASS=A, SERVER=A, SERVICE=A
CLASS=B, SERVER=B, SERVICE=B, SHORT-BUFFER-LIMIT=100
CLASS=C, SERVER=C, SERVICE=C
```

Dynamic Memory Management

Dynamic memory management is a feature to handle changing Broker workload without any restart of the Broker task. It increases the availability of the Broker by using various memory pools for various Broker resources and by being able to use a variable number of pools for the resources.

If more memory is needed than currently available, another memory pool is allocated for the specific type of resource. If a particular memory pool is no longer used, it will be deallocated.

The following Broker attributes can be omitted if DYNAMIC-MEMORY-MANAGEMENT=YES has been defined:

■ NUM-CLIENT	NUM-PUBLISHER	NUM-SUBSCRIBER-TOTAL
NUM-CMDLOG-FILTER	NUM-SERVER	NUM-TOPIC
NUM-COMBUF	NUM-SERVICE	NUM-TOPIC-EXTENSION
NUM-CONV[ERSATION]	NUM-SERVICE-EXTENSION	NUM-TOPIC-TOTAL
NUM-LONG[-BUFFER]	NUM-SHORT[-BUFFER]	NUM-UOW MAX-UOWS MUOW
■ NUM-PUBLICATION	NUM-SUBSCRIBER	NUM-WQE

If you want statistics on allocation and deallocation operations in Broker, you can configure Broker to create a storage report with the attribute STORAGE-REPORT. See *Storage Report* below.

Note: To ensure a stabile environment, some pools of Broker are not deallocated automatically. The first pools of type COMMUNICATION, CONVERSATION, CONNECTION, HEAP, PARTICIPANT, PARTICIPANT EXTENSION, SERVICE ATTRIBUTES, SERVICE, SERVICE EXTENSION, TIMEOUT QUEUE, TRANSLATION, WORK QUEUE are excluded from the automatic deallocation even when they have not been used for quite some time. Large pools cannot be reallocated under some circumstances if the level of fragmentation in the address space has been increased in the meantime.

Dynamic Worker Management

Dynamic worker management is a feature to handle the fluctuating broker workload without restarting the Broker task. It adjusts the number of running worker tasks according to current workload. The initial portion of worker tasks started at Broker startup is still determined by NUM-WORKER.

If more workers are needed than currently available, another worker task is started. If a worker task is no longer needed, it will be stopped.

The following Broker attributes are used for the configuration if DYNAMIC-WORKER-MANAGEMENT=YES has been defined:

- WORKER-MAX
- WORKER-MIN
- WORKER-NONACT
- WORKER-QUEUE-DEPTH
- WORKER-START-DELAY

The following two attributes are very performance-sensitive:

• Attribute WORKER-QUEUE-DEPTH defines the number of unassigned user requests in the input queue before a new worker task is started.

Attribute WORKER-START-DELAY defines the time between the last worker task startup and the next check for another possible worker task startup. It is needed to consider the time for activating a worker task.

Both attributes depend on the environment, in particular the underlying operating system and the hardware. The goal is to achieve high-performance user request processing without starting too many worker tasks.

A good starting point to achieve high performance is not to change the attributes and to observe the performance of the application programs after activating the dynamic worker management.

If broker attribute DYNAMIC-WORKER-MANAGEMENT=YES is set, operator commands are available under z/OS to deactivate and subsequently reactivate dynamic worker management.

The following section illustrates the two different modes of dynamic worker management:

Scenario 1

```
DYNAMIC-WORKER-MANAGEMENT=YES
NUM-WORKER = 5
WORKER-MIN = 1
WORKER-MAX = 32
```

Broker is started with 5 worker tasks and then dynamically varies the number of worker tasks within the range from WORKER-MIN=1 to WORKER-MAX=32 due to DYNAMIC-WORKER-MANAGEMENT=YES.

Scenario 2

```
DYNAMIC-WORKER-MANAGEMENT=NO
NUM-WORKER = 5
WORKER-MIN = 1
WORKER-MAX = 32
```

Broker is started with 5 worker tasks. The WORKER-MIN/MAX attributes are ignored due to DYNAMIC-WORKER-MANAGEMENT=NO.

Storage Report

You can create an optional report file that provides details about all activities to allocate or to deallocate memory pools. This section details how to create the report and provides a sample report.

- Creating a Storage Report
- Platform-specific Rules
- Sample Storage Report

See also Broker-specific attribute STORAGE-REPORT.

Creating a Storage Report

Use Broker's global attribute STORAGE-REPORT with the value YES. If attribute value YES is supplied, all memory pool operations will be reported if the output mechanism is available. If the value NO is specified, no report will be created.

Platform-specific Rules

z/OS

DDNAME ETBSREP assigns the report file. Format RECFM=FB, LRECL=121 is used.

UNIX and Windows

Broker creates a file with the name *STORAGE.REPORT* in the current working directory. If the environment variable ETB_STORAGE_REPORT is supplied, the file name specified in the environment variable will be used. If Broker receives the command-line argument - r, the token following argument - r will be used as the file name.

BS2000/OSD

LINK-NAME ETBSREP assigns the report file. Format REC-FORM=V, REC-SIZE=O, FILE-TYPE ISAM is used by default.

z/VSE

Logical unit SYS015 and logical file name *ETBSREP* are used. Format RECORD-FORMAT=FB, RECORD-LENGTH=121 is used.

Sample Storage Report

The following is an excerpt from a sample STORAGE report.

Header	Description
Identifier	Name of the memory pool.
Address	Start address of the memory pool.
Size	Size of the memory pool.
Total	Total size of all obtained memory pools.
Date, Time	Date and time of the action.

Header	Description
	The action of Broker. The following actions are currently supported: Allocated: memory pool is allocated . Deallocated: memory pool is deallocated.

Maximum TCP/IP Connections per Communicator

This table shows the maximum number of TCP/IP connections per communicator:

Platform	Maximum Number of TCP/IP Connections per Communicator
AIX	2,048
BS2000/OSD	2,048
HP-UX	2,048
Linux	4,096
Solaris	65,356
Windows	4,096
z/OS	16,384
z/VSE	2,048

With the Broker-specific attribute POLL, these restrictions can be lifted under z/OS, UNIX and z/VSE. See POLL.

See also MAX-CONNECTIONS under *TCP-OBJECT* (*Struct INFO_TCP*) under *Information Reply Structures* in the Broker CIS documentation.

Note for z/OS

Under z/OS, the following message may appear in the broker log:

```
ETBD0286 Diagnostic Values:
accept: 124, EDC5124I Too many open files.errno2: 84607302 050B0146
```

The most common reason for this TCP/IP Communicator diagnostic message is the limitation of open files per user. The value of MAXFILEPROC in the BPXPRM00 parmlib member should be greater than the expected number of TCP/IP connections.

Note for UNIX

Under UNIX, you can use the following command to display the maximum number of open files in the operating system shell.

ulimit -n

This value should be greater than the expected number of TCP/IP connections.

Variable Definition File	

Note: This section lists all EntireX Broker parameters. Not all parameters are applicable to all supported operating systems.

The Broker attribute file contains a series of parameters (attributes) that control the availability and characteristics of clients and servers, publishers and subscribers as well as of the Broker itself. You can customize the Broker environment by modifying the attribute settings.

Name and Location of Attribute File

The name and location of the broker attribute file is platform-dependent.

Platform	File Name/Location
z/OS	Member <i>EXBATTR</i> in the EntireX Broker source library.
UNIX	File <i>etbfile</i> in directory < <i>InstDir</i> >/EntireX/config/etb/< <i>BrokerName</i> > (default) *
Windows	<pre>File <brokername>.atr in directory <instdir>\EntireX\config\etb\<brokername>(default) *</brokername></instdir></brokername></pre>
BS2000/OSD	File ETB-ATTR in library EXX960.JOBS.
z/VSE	Library member <i>ETBnnn.ATR</i> , where <i>nnn</i> is a placeholder specifiying the broker instance (e.g. <i>nnn</i> = the assigned broker ID).

* When starting a broker manually, name and location of the broker attribute file can be overwritten with the environment variable ETB_ATTR.

Attribute Syntax

Each entry in the attribute file has the format:

ATTRIBUTE-NAME=value

The following rules and restrictions apply:

- A line can contain multiple entries separated by commas.
- Attribute names can be entered in mixed upper and lowercase.
- Spaces between attribute names, values and separators are ignored.
- Spaces in the attribute names are not allowed.
- Commas and equal signs are not allowed in value notations.
- Lines starting with an asterisk (*) are treated as comment lines. Within a line, characters following an * or # sign are also treated as comments.
- The CLASS keyword must be the first keyword in a service definition.
- Multiple services can be included in a single service definition section. The attribute settings will apply to all services defined in the section.
- Multiple topics can be included in a single topic definition section. The attribute settings will apply to all topics defined in the section.

- Attributes specified after the service definition (CLASS, SERVER, SERVICE *keywords*) overwrite the default characteristics for the service.
- Attributes specified after the topic definition (TOPIC keyword) override the default characteristics for the topic.
- Attribute values can contain variables of the form *\${variable name}* or *\$variable name*:
 - Due to variations in EBCDIC codepages, braces should only be used on ASCII (UNIX or Windows) platforms or EBCDIC platforms using the IBM-1047 (US) codepage.
 - The variable name can contain only alphanumeric characters and the underscore (_) character.
 - The first non-alphanumeric or underscore character terminates the variable name.
 - under UNIX and Windows, the string \${variable name} is replaced with the value of the corresponding environment variable.
 - On z/OS, variable values are read from a file defined by the DD name ETBVARS. The syntax of this file is the same as the attribute file.
 - If a variable has no value: if the variable name is enclosed in braces, error 00210594 is given, otherwise \$variable name will be used as the variable value.
 - If you encounter problems with braces (and this is quite possible in a z/OS environment), we suggest you omit the braces.

Broker-specific Attributes

The broker-specific attribute section begins with the keyword DEFAULTS=BROKER. It contains attributes that apply to the broker. At startup time, the attributes are read and duplicate or missing values are treated as errors. When an error occurs, the broker stops execution until the problem is corrected.

9

Tip: To avoid resource shortages for your applications, be sure to specify sufficiently large values for the broker attributes that define the global resources.

Caution: A value of 0 (zero) is invalid. If you set this value too low, additional overhead is required for starting and stopping worker tasks. The default and recommended value is 70S. 									
WORKER-START-DELAY	<i>n</i> Delay is extended b Delay after a successfu can be started to hand to avoid the risk of rec worker task itself caus If no value is specified	value will result in longer broker response times. <i>internal-value</i> <i>n</i> O z u w b <i>n</i> Delay is extended by <i>n</i> seconds. Delay after a successful worker task invocation before another worker task can be started to handle current incoming workload. This attribute is used to avoid the risk of recursive invocation of worker tasks, because starting worker task itself causes workload increase. If no value is specified, an internal value calculated by the broker is used to optimize dynamic worker management. This calculated value is the									

Service-specific Attributes

Each section begins with the keyword DEFAULTS=SERVICE. Services with common attribute values can be grouped together. The attributes defined in the grouping apply to all services specified within it. However, if a different attribute value is defined immediately following the service definition, that new value applies. See also the sections *Wildcard Service Definition* and *Service Update Modes* below the table.

		Operating System

	If the unit of work (UOW) is inactive, that is, not processed within the time limit, it is deleted and given a status of TIMEOUT. This attribute can be overridden by the UWTIME field in the Broker ACI control block.						

Wildcard Service Definition

The special names of CLASS = *, SERVER = * and SERVICE = * are allowed in the service-specific section of the broker attribute file. These are known as "wildcard" service definitions. If this name is present in the attribute file, any service that registers with the broker and does not have its own entry in the attribute file will inherit the attributes that apply to the first wildcard service definition found.

For example, a server that registers with CLASS=ACLASS, SERVER=ASERVER and SERVICE=ASERVICE can inherit attributes from any of the following entries in the attribute file (this list is not necessarily complete):

```
CLASS = *, SERVER = ASERVER, SERVICE = ASERVICE
CLASS = ACLASS, SERVER = *, SERVICE = *
CLASS = *, SERVER = *, SERVICE = *
```

Of course, if there is a set of attributes that are specifically defined for CLASS=ACLASS, SERVER=ASERV-ER, SERVICE=ASERVICE, then all of the wildcard service definitions will be ignored in favor of the exact matching definition.

Service Update Modes

EntireX has two modes for handling service-specific attributes. See broker-specific attribute SER-VICE-UPDATES.

- In service update mode (SERVICE-UPDATES=YES), the service configuration sections of the attribute file are read whenever the first replica of a particular service registers.
- In non-update mode (SERVICE-UPDATES=NO), the attribute file is not reread. All attributes are read during startup and the broker does not honor any changes in the attribute file. This mode is useful if
 - there is a high frequency of REGISTER operations, or
 - the attribute file is rather large and results in a high I/O rate for the broker.

The disadvantage to using non-update mode is that if specific attributes are modified, the broker must be restarted to effect the changes. Generally, this mode should be used only if the I/O rate of the broker is considerably high, and if the environment seldom changes.

OPTION Values for Conversion

The different option values allow you to either handle character conversion deficiencies as errors, or to ignore them:

- 1. Do not ignore any character conversion errors and force an error always (value STOP). This is the default behavior.
- 2. Ignore if characters can not be converted into the receiver's codepage, but force an error if sender characters do not match the sender's codepage (value SUBSTITUTE-NONCONV).
- 3. Ignore any character conversion errors (values SUBSTITUTE and BLANKOUT).

The situations 1 and 2 above are reported to the broker log file if TRACE option for CONVERSION is set to level 1.

		Options Su	pported for	if TRACE	in Broker Log File Option for DN is set to 1
Value	Description	SAGTCHA		Bad Input Characters (Sender's Codepage)	Non-convertible Characters (Receiver's Codepage)
SUBSTITUTE	Substitutes both non-convertible characters (receiver's codepage) and bad input characters (sender's codepage) with a	yes	yes	No message.	No message

				Report Situation	in Broker Log File
				if TRACE	Option for
		Options Su	pported for	CONVERSI	ON is set to 1
Value	Description	SAGTCHA	SAGTRPC	Bad Input Characters (Sender's Codepage)	Non-convertible Characters (Receiver's Codepage)
	codepage-dependent default replacement character.				
SUBSTITUTE-NONCONV	If a corresponding code point is not available in the receiver's codepage, the character cannot be converted and is substituted with a codepage-dependent default replacement character. Bad input characters in sender's codepage are not substituted and result in an error.	yes	yes	Write detailed conversion error message.	No message.
BLANKOUT	Substitutes non-convertible characters with a codepage-dependent default replacement; blanks out the complete RPC IDL field containing one or more bad input characters.	no	yes	No message.	No message.
STOP	Signals an error on detecting a non-convertible or bad input character. This is the default behavior if no option is specified.	yes	yes	conversion	Write detailed conversion error message.

Topic-specific Attributes

The topic-specific attribute section begins with the keyword DEFAULTS=TOPIC as shown in the sample attribute file. It contains attributes that apply to the publish and subscribe communication model.

Codepage-specific Attributes

The codepage-specific attribute section begins with the keyword DEFAULTS=CODEPAGE as shown in the sample attribute file. You can use the attributes in this section to customize the broker's locale string defaults and customize the mapping of locale strings to codepages for the internationalization approaches ICU conversion and SAGTRPC user exit. These attributes do not apply to other approaches. See *Internationalization with EntireX* for more information.

				Oķ	perating System	em			
Attribute	Values	Opt/ Req	SO/Z	UNIX	Windows	zWSE	BS2000		
DEFAULT_ASCII	Any ICU converter name or alias. See also <i>Additional</i> <i>Notes</i> below.	0	Z	u	W	v	b		
	 Customize the broker's locale string defaults by assigning the default codepage for EntireX components (client or server, publisher or subscriber). See <i>Broker's Locale String Defaults</i> under <i>Locale String Mapping</i> in the internationalization documentation. This value is used instead of the broker's locale string defaults if the calling component does not send a locale string itself, and the calling component is running on an ASCII platform (UNIX, Windows, etc. and one of the internationalization approaches ICU conversion or SAGTRPC user exit is used. See <i>ICU Conversion</i> under <i>Introduction to Internationalization</i> and <i>SAGTRPC User Exit</i> under <i>Introduction to Internationalization</i>. 								
	DEFAULTS=CODEPAGE /* Broker Locale String Defaults */ DEFAULT_ASCII=windows-950 For more examples, see <i>Configuring Broker's Locale String Defaults</i> under <i>Locale</i> <i>String Mapping</i> in the internationalization documentation and also <i>Additional</i> <i>Notes</i> below.

Additional Notes

- Locale string matching is case insensitive when bypassing the broker's built-in mechanism, that is, when the broker examines the codepages section in the attribute file.
- If ICU is used for the internationalization approach and if the style in not known by ICU, e.g. ECSnnnn, <ll>_<cc> etc., the name will be mapped to a suitable ICU alias. For more details on the mapping mechanism, see Broker's Built-in Locale String Mapping under Locale String Mapping in the internationalization documentation. For more details on ICU and ICU converter name standards, see ICU Resources under Introduction to Internationalization.
- If SAGTRPC user exit is used for the internationalization approach, we recommend assigning the codepage in the form CP<nnnn>. To determine the number given to SAGTRPC user exit, see Broker's Built-in Locale String Mapping under Locale String Mapping in the internationalization documentation.
- See CONVERSION and CONVERSION attribute CONVERSION on this page for the internationalization approach in use.

Adabas SVC/Entire Net-Work-specific Attributes

The Adabas SVC/Entire Net-Work-specific attribute section begins with the keyword DEFAULTS=NET as shown in the sample attribute file. The attributes in this section are needed to execute the Adabas SVC/Entire Net-Work communicator of the EntireX Broker kernel.

Note: This section applies to mainframe platforms only. It does not apply to UNIX and Windows.

TCP/IP-specific Attributes

The TCP/IP-specific attribute section begins with the keyword DEFAULTS=TCP as shown in the sample attribute file. It contains attributes that apply to the TCP/IP transport communicator. The transport is activated by TRANSPORT=TCP in the Broker-specific section of the attribute file. A maximum of five TCP/IP communicators can be activated by specifying up to five HOST/PORT pairs.

			Operating System				
Attribute	Values	Opt/ Req	SOIZ	NNX	Windows	zNSE	BS2000
	Database ID of Adabas database where the persistent store resides.						
FNR	1 - 32535	R	Z	u	w	v	b
	File number of broker persistent store file.						
FORCE-COLD	<u>N</u> Y	0	Z	u	w	v	b
	Determines whether a broker cold start is permitted to overwrite a persistent store file that has been used by another broker ID and/or platform. Specify Y to allow existing information to be overwritten.						
MAXSCAN	0- <i>n</i>	0	Z	u	w	V	b
	Limits display of persistent UOW information in the persistent store through Command and Information Services. Default value is 1000.						
OPENRQ	<u>N</u> Y	0	Z	u	W	V	b
	Determines whether driver for Adabas persistent store is to issue an OPEN command to Adabas.						
SVC	200-255	R	Z			V	
	Use this parameter to specify the Adabas SVC number to be used by the Adabas persistent store driver.						
TRACE-LEVEL	0-8	0	Z	u	W	V	b
	Trace level for Adabas persistent store. It overrides the global value of trace level in the attribute file.						

Variable Definition File

The broker attribute file contains the configuration of one EntireX Broker instance. In order to share attribute files between different brokers, you identify the attributes that are unique and move them to a variable definition file. This file enables you to share one attribute file among different brokers. Each broker in such a scenario requires its own variable definition file.

The following attributes are considered unique for each machine:

- BROKER-ID (in Broker-specific attributeBROKER-ID)
- NODE (in Entire Net-Work-specific attribute NODE)
- PORT (in PORT (SSL) and PORT (TCP/IP))

How you use the variable definition file will depend upon your particular needs. For instance, some optional attributes may require uniqueness - for example, DBID and FNR in DEFAULTS=ADABAS - so that you may specify the persistent store.

Concepts of Persistent Messaging

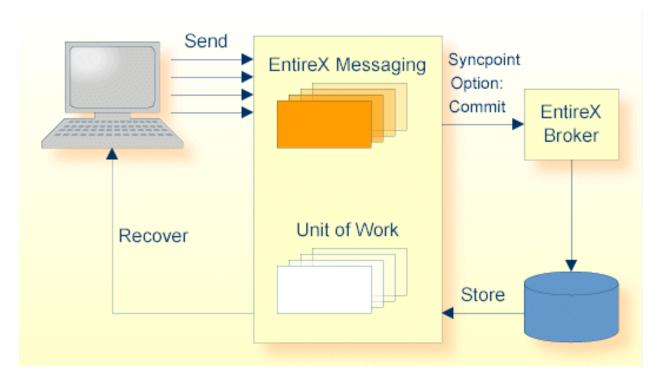

Client Server Model: Persistent Messaging	108
Publish-and-Subscribe Model: Persistent Behavior	109
Definitions of Persistent Messaging Terms	111
Availability of Persistent Store	113
Migrating the Persistent Store	115
Persistent Store Report	118
Swapping out New Units of Work	121

This chapter provides a brief introduction to the concepts of the persistent store and its role in EntireX for providing persistent messaging within the client/server model and also for publish-and-subscribe functionality. It covers the following topics:

The table *Persistent Store Drivers* lists the implementation choices available to each operating system for accessing the physical persistent store. See also *Using Persistence and Units of Work*, *Broker UOW Status Transition* under *Concepts of Persistent Messaging* and *Managing the Broker Persistent Store* in the platform-specific administration documentation.

Client Server Model: Persistent Messaging

EntireX provides persistent messaging within the client/server model. This is achieved by storing all persistent messages on disk so that if a system failure occurs, messages will automatically be recovered allowing applications to be restarted without any loss of data. The section *Using Persistence and Units of Work* describes implementation issues and how to use persistence and units of work in EntireX Broker. Units of work can also be used without persistence; units of work which are the vehicle for persistent messaging.

The following figure illustrates the concept of persistent messages.

Persistence in an EntireX Broker's unit of work (a group of logically related messages) has the following four variations:

Both the unit of work and its status have persistence.

- The unit of work does not have persistence, but its status does.
- The unit of work has persistence, but its status does not.
- Neither the unit of work nor its status has persistence.

The status of a message is information about the message rather than the actual message data itself. This enables the sender to determine the progress of the message and determine if it has been received by the partner and whether processing was successfully completed. This gives applications the option of having the Broker kernel store only the message status and not the message itself, provided the application has been written to resend data from a known point in the event of system failure. This option can afford significant performance benefits over storing the whole message data.

To support transaction control in a coordinated operation of distributed systems, EntireX can group logically related messages into "units of work" that are committed to the EntireX Broker for further transmission when complete. In case of failure on the server side, the receiving program can backout the whole unit of work; this makes it available for processing later or by another server.

Publish-and-Subscribe Model: Persistent Behavior

EntireX provides persistent publish-and-subscribe behavior by writing information to disk in order to protect against system failures. This allows applications to be restarted without any loss of the following types of data:

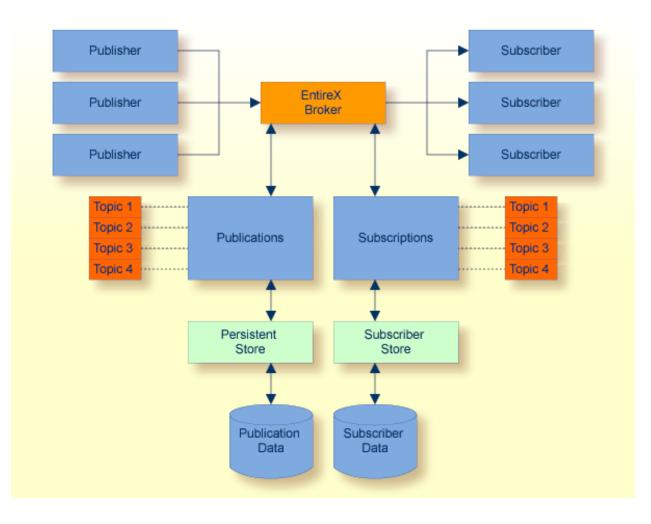

Durable Subscription Information

This comprises a list of subscribers and the topics to which they have durably subscribed. This ensures that users only have to subscribe once to a topic; their persistent status remains after Broker is restarted. If the persistent store is used to maintain subscription status, you must define the SUBSCRIPTION-EXPIRATION options.

Publication Data

This data is also persisted if the administrator has defined this characteristic for the topic.

The diagram below shows the two types of publish-and-subscribe information which is written to the persistent store.

Definitions of Persistent Messaging Terms

- UOW
- Persistent Store
- Persistent Store Drivers
- UOW Lifetime
- Persistent UOW
- Persistent Status
- Publication
- Durable Subscription
- Publication Lifetime
- Subscription Expiration

UOW

A unit of work (UOW) is a set of one or more messages that are processed as a single unit. The sender of a UOW adds messages to the UOW and then indicates that the UOW is complete (COMMIT). The UOW and its messages are not visible to the receiver until the sender has committed the UOW. Once the UOW is committed, the receiver can receive the messages, and can indicate when the UOW is complete (COMMIT).

Persistent Store

The persistent store is used for storing unit-of-work messages and publish-and-subscribe data to disk. This means message and status information can be recovered after a hardware or software failure to the previous commit point issued by each application component.

Persistent Store Drivers

A persistent store driver is an executable, or a load module, that implements access to the physical persistent store. There is one persistent store driver for each persistent store type. The following table shows the persistent store options:

Persistent Store Type	Description	Operating System	Notes
Adabas	Uses Adabas database.	UNIX, Windows, z/OS, z/VSE	Adabas, Software AG's ADAptable dataBASe, is a high-performance, multithreaded, database management system.
DIV	Uses IBM Data In Virtual facility on z/OS.	z/OS	This persistent store option is implemented as a VSAM linear data set.

Persistent Store Type	Description	Operating System	Notes
CTREE	c-tree© is an embedded local	UNIX and Windows	c-tree© is the fast and reliable embedded
	database that can be used as your persistent store.		database of FairCom Corporation®.

See also *Managing the Broker Persistent Store* in the platform-specific administration documentation and also PSTORE-TYPE under *Broker Attributes* in the platform-independent administration documentation.

UOW Lifetime

Each UOW has a lifetime value associated with it. This is the period of time that the UOW is allowed to exist without being completed. This time starts when the UOW is initially created and runs until the UOW is completed. A UOW is completed when it is successfully:

- cancelled or backed out by its sender, or
- cancelled or committed by its receiver.

If the UOW is in ACCEPTED status when this lifetime expires, the UOW is placed into a TIMEOUT status. Lifetime timeouts will not occur when the UOW is in either RECEIVED or DELIVERED status.

A special "pseudo-clock" is maintained for UOW lifetimes. This clock is implemented in such a way that it only runs when the Broker is active. This prevents a UOW lifetime from expiring while the Broker is down or otherwise unavailable.

Persistent UOW

Persistence is an attribute of a UOW (unit of work). If a UOW is persistent, its messages are saved in the persistent store when the sender COMMITS the UOW and they are retained until the receiver COMMITS or CANCELS the UOW, or until its lifetime expires. If the Broker or system should fail after the UOW is committed by the sender, the UOW (and its conversation) will be restored to their last, stable status when the Broker restarts.

Persistent Status

Persistent status is an attribute of a UOW (unit of work). If a UOW has persistent status, the status of the UOW is maintained in the persistent store, and is updated whenever the status changes. The persistent status remains in the persistent store after the UOW is completed, until its status lifetime has expired.

A persistent status value represents a multiple of the UOW lifetime value. Thus if a UOW has a lifetime of 5M (whereby M stands for minutes) and a persistent status value of 4, the status of the UOW would be deleted 20M (5M*4) after the UOW was completed.

Publication

A publication is one or more messages forming an atomic unit and sent by a publisher to a topic. Subscribers are then able to receive publications committed after the time at which a subscriber first subscribes.

Durable Subscription

Subscribers inform EntireX of their intent to receive publications by issuing a SUBSCRIBE command and specifying the topic of interest. If the administrator has specified this topic to the Broker attribute file with a characteristic of DURABLE, users will be able to subscribe to the topic durably. This means that the user's subscription status remains after EntireX is restarted.

Publication Lifetime

A characteristic of the topic is the lifetime which publications will live and be available to subscribers. Once a publication has been received by all eligible subscribers, it will be removed automatically, even before its lifetime has been reached.

Subscription Expiration

Subscribers inform EntireX of their intent to receive publications by issuing a SUBSCRIBE command and specifying the topic of interest. If the administrator has specified this topic to the Broker attribute file with a characteristic of DURABLE, all user subscriptions to that topic will be durable. This means that the user's subscription status remains after EntireX is restarted.

Availability of Persistent Store

- **Caution:** The persistent store must be available before you attempt to start or restart the Broker; otherwise your Broker will not initialize.
 - Introduction
 - Disconnect the Persistent Store

Connect the Persistent Store

Introduction

The PSTORE must be available for the Broker to start. Subsequently, Broker will continue to function even if the PSTORE becomes unavailable and applications issuing non-persistent commands will continue without interruption. However, Broker will not be able to process commands relating to persistence until the PSTORE becomes available again.

Users issuing commands involving persistence - for example units of work with persistence and durable publish and subscribe - are notified of the unavailability of the PSTORE through an ACI return code. In addition, persistent commands being processed at the point of unavailability are backed out, and details of the PSTORE problem are written to the Broker log file.

There are several reasons for the PSTORE becoming unavailable. Examples:

- unavailability of the PSTORE file(s)
- capacity of PSTORE file being exceeded
- in the case of Adabas, termination of the database

Disconnect the Persistent Store

You can remove the state "No new Units of Work" - that is, no new persistent data - using CIS. If the PSTORE capacity is exceeded, an error message is written to the Broker log file. You must use Command and Information Services (CIS) to ensure that users cannot issue further commands creating new units of work or publications.

During the time the PSTORE is unavailable, there is no timeout processing for unit-of-work and publication records kept in the PSTORE. In addition, some in-memory resources relating to persistent items, such as conversation control blocks, are also retained until the PSTORE becomes available again and normal processing is resumed for all commands.

See executable command request DISCONNECT-PSTORE under ETBCMD: Executable Command Requests under Broker Command and Information Services.

Connect the Persistent Store

Subsequently, you can use CIS to make the PSTORE available again, allowing users only to issue commands consuming records from the PSTORE rather than producing new ones. After a period of operation in this state, the contents of the PSTORE will be reduced sufficiently, and you can remove the state "No new Units of Work" through CIS.

See executable command request CONNECT-PSTORE under ETBCMD: Executable Command Requests under Broker Command and Information Services.

Migrating the Persistent Store

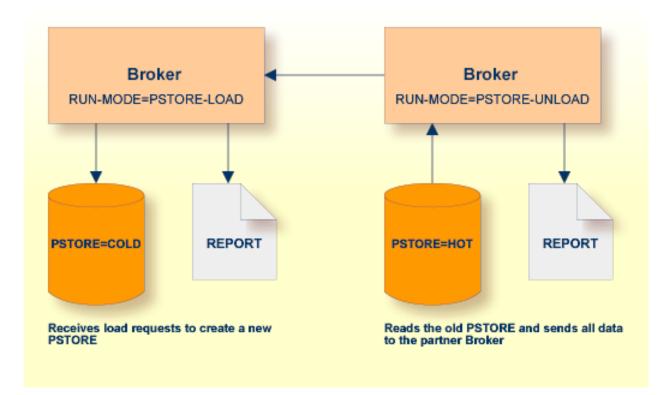

- Introduction
- Configuration
- Migration Procedure

Introduction

The contents of EntireX Broker's persistent store can be migrated to a new persistent store in order to change the PSTORE type or to use the same type of PSTORE with increased capacity.

The migration procedure outlined here requires two Broker instances started with a special RUN-MODE parameter. One Broker unloads the contents of the persistent store and transmits the data to the other Broker, which loads data into the new PSTORE. Therefore, for the purposes of this discussion, we shall refer to an *unload* Broker and a *load* Broker.

This procedure is based on Broker-to-Broker communication to establish a communication link between two Broker instances. It does not use any conversion facilities, since the migration procedure is supported for homogeneous platforms only.

Configuration

The migration procedure requires two Broker instances, each started with the RUN-MODE attribute. The unload Broker should be started with the following attribute:

RUN-MODE=PSTORE-UNLOAD

The load Broker should be started with the following attribute:

RUN-MODE=PSTORE-LOAD

These commands instruct the Broker instances to perform the PSTORE migration.

Note: The attribute PARTNER-CLUSTER-ADDRESS must be defined in both Broker instances to specify the transport address of the load Broker. The unload Broker must know the address of the load broker, and the load Broker must in turn know the address of the unload Broker.

Example:

Broker ETB001 performs the unload on host HOST1, and Broker ETB002 performs the load on host HOST2. The transmission is based on TCP/IP. Therefore, Broker ETB001 starts the TCP/IP communicator to establish port 1971, and Broker ETB002 starts the TCP/IP communicator to establish port 1971.

For ETB001, attribute PARTNER-CLUSTER-ADDRESS = HOST2:1972:TCP is set, and for ETB002, attribute PARTNER-CLUSTER-ADDRESS = HOST1:1971:TCP is set to establish the Broker-to-Broker communication between the two Broker instances.

In addition to attributes RUN-MODE and PARTNER-CLUSTER-ADDRESS, a fully functioning Broker configuration is required when starting the two Broker instances. To access an existing PSTORE on the unloader side, you must set the attribute PSTORE = HOT. To load the data into the new PSTORE on the loader side, you must set the attribute PSTORE = COLD. The load process requires an empty PSTORE at the beginning of the load process.

Note: Use caution not to assign PSTORE = COLD to your unload Broker instance, as this startup process will erase all data currently in the PSTORE.

For the migration process, the unload Broker and the load Broker must be assigned different persistent stores.

A report can be generated to detail all of the contents of the existing persistent store. At the end of the migration process, a second report can be run on the resulting new persistent store. These two reports can be compared to ensure that all contents were migrated properly. To run these reports, set the attribute PSTORE - REPORT = YES. See PSTORE under *Broker Attributes* in the platform-independent administration documentation for a detailed description, especially for the file assignment.

Migration Procedure

The migration procedure is made up of three steps.

Step 1

The unload Broker and the load Broker instances can be started independently of each other. Each instance will wait for the other to become available before starting the unload/load procedure.

The unload Broker instance sends a handshake request to the load Broker instance in order to perform an initial compatibility check. This validation is performed by Broker according to platform architecture type and Broker version number. The handshake ensures a correctly configured partner cluster address and ensures that the user did not assign the same PSTORE to both Broker instances. If a problem is detected, an error message will be issued and both Broker instances will stop.

Step 2

The unload Broker instance reads all PSTORE data in a special non-destructive raw mode and transmits the data to the load Broker instance. The load Broker instance writes the unchanged raw data to the new PSTORE. A report is created if PSTORE-REPORT = YES is specified, and a valid output file for the report is specified.

Step 3

The unload Broker instance requests a summary report from the load Broker instance to compare the amount of migrated data. The result of this check is reported by the unload Broker instance and the load Broker instance before they shut down.

When a Broker instances is started in RUN-MODE = PSTORE-LOAD or RUN-MODE = PSTORE-UNLOAD, the Broker instances only allow administration requests. All other user requests are prohibited.

- 1. The contents of the persistent store are copied to the new persistent store as an exact replica. No filtering of unnecessary information will be performed - for example, UOWs in received state. The master records will not be updated.
- 2. Before restarting your Broker with the new persistent store, be sure to change your PSTORE attribute to PSTORE = HOT. *Do not* start your broker with the new persistent store using PSTORE = COLD; this startup process will erase all of the data in your persistent store.
- 3. After completing the migration process and restarting your Broker in a normal RUN-MODE, it is important not to bring both the new PSTORE and the old PSTORE back online using separate Broker instances; otherwise, applications would receive the same data twice. Once the migration process is completed satisfactorily, and is validated, the old PSTORE contents should be discarded.

Persistent Store Report

You can create an optional report file that provides details about all records added to or deleted from the persistent store. This section details how to create the report and provides a sample report.

- Configuration
- Sample Report

Configuration

To create a persistent store report, use Broker's global attribute PSTORE-REPORT with the value YES.

When the attribute value YES is supplied, all created or deleted persistent records will be reported if the output mechanism is available.

If the value NO is specified, no report will be created.

The report file is created using the following rules:

BS2000/OSD

LINK-NAME ETBPREP assigns the report file. Format REC-FORM=V, REC-SIZE=O, FILE-TYPE ISAM is used by default.

UNIX

Broker creates a file with the name *PSTORE.REPORT* in the current working directory. The file name *PSTORE.REPORT.LOAD* will be used if Broker is started with RUN-MODE = PSTORE-LOAD.

The file name *PSTORE.LOAD.UNLOAD* will be used if Broker is started with RUN-MODE = PSTORE-UNLOAD.

If the environment variable ETB_PSTORE_REPORT is supplied, the file name specified in the environment variable will be used.

If Broker receives the command-line argument -p, the token following argument -p will be used as the file name.

Windows

Same as UNIX.

z/OS

DDNAME ETBPREP assigns the report file. Format RECFM=FB, LRECL=121 is used.

z/VSE

Logical unit SYS003 and logical file name *ETBPREP* are used. Format RECORD-FORMAT = FB, RECORD-LENGTH = 121 is used.

Sample Report

The following is an excerpt from a sample PSTORE report.

EntireX 8.0.0.00	PSTORE	Report 2	2008-02-21 17:1	8:38 Pag	e 1

The following fields are provided in the report:

- Identifier provides the UOWID (record ID).
- Elements gives the number of messages per UOW when creating or loading records.
- Total Length gives the size of the raw record when creating or loading records.
- Record Type describes the type of the data. Following types are currently supported:
 - Cluster: a special record for synchronization purposes
 - Conversation: a unit of work as part of a conversation
 - Master: a special record to manage the persistent store
 - Publication: a record containing a publication for a durable topic
 - Subscription: a record containing subscriber data (if SUBSCRIBER-STORE = PSTORE) is defined
- Date and time of the action
- Action describes the action of Broker. The following actions are currently supported:
 - Created: record is created
 - Deleted: record is deleted
 - Loaded: record is loaded (Broker instance with RUN-MODE = PSTORE-LOAD)
 - Unloaded: record is unloaded (Broker instance with RUN-MODE = PSTORE-UNLOAD)

Swapping out New Units of Work

The broker processes UOWs in memory. However, if a client produces a large number of UOWs and no server is available, or the server cannot handle all data, the number of UOWs in memory may increase and reach a critical limit.

To avoid an overload of UOWs in memory, EntireX Broker can swap out new conversations that containing UOWs (STORE=BROKER) and that have been accomplished by the client with an EOC. The data is persisted on PSTORE and there is no need to keep the data in memory unless a server wants to receive the data.

Activate the swap-out feature with the broker-specific attribute SWAP-OUT-NEW-UOWS. It is not activated by default. However, the swap-out feature can be configured per service to define a minimum portion of UOWs kept in memory. Use the service-specific attribute MIN-UOW-CONVERSATIONS-IN-MEMORY to define this portion.

Using Persistence and Units of Work

Implementation Issues	124
Using Units of Work	
Using Persistence	133
Using Persistent Status	138
Recovery Processing	140

This chapter describes implementation issues and how to use persistence and units of work in EntireX Broker. It assumes you are familiar with EntireX Broker from both an administrative and an application perspective, and with the ACI programming in particular. See also *EntireX Broker* and *EntireX Broker ACI Programming*.

Implementation Issues

- Table of Persistent Store Drivers
- Changes are Required
- Attributes used for Units of Work
- ACI Fields used for Units of Work
- ACI Function SYNCPOINT used for Units of Work
- Options used for UOW Operations
- CID Implementation: Numeric Digits, Characters 0-9 and A-Z

Table of Persistent Store Drivers

A persistent store driver is an executable, or a load module that implements access to the physical persistent store. There is one persistent store driver for each persistent store type. The following table shows the persistent store options:

Persistent Store Type	Description	Operating System	Notes
Adabas	Uses Adabas database.	UNIX, Windows, z/OS, z/VSE	Adabas, Software AG's ADAptable dataBASe, is a high-performance, multithreaded, database management system.
DIV	Uses IBM Data In Virtual facility on z/OS.	z/OS	This persistent store option is implemented as a VSAM linear data set.
CTREE	c-tree© is an embedded local database that can be used as your persistent store.	UNIX and Windows	c-tree© is the fast and reliable embedded database of FairCom Corporation®.

Changes are Required

It is important to note that some level of both application and system changes are necessary to utilize UOWs. Existing message-based Broker applications will continue to operate as before.

Attributes used for Units of Work

The following table represents the keyword parameters that can be used in the Broker attribute file for UOWs. A short form of the keyword is given if applicable. Default values are underlined.

Keyword	Value	Description
STORE	<u>OFF</u> I BROKER	Broker: sets default STORE attribute for all units of work.
		Service: sets default STORE attribute for units of work sent to the service.
MAX-UOWS or MUOW	<u>0</u> <i>n</i>	Broker: maximum number of active UOWs. If 0 is specified, then the Broker will not support any UOW operations.
		Service: maximum number of active UOWs for a service.
MAX-MESSAGES-IN-UOW or UMSG	<u>16</u> <i>n</i>	Broker: maximum number of messages in a UOW.
		Service: maximum number of messages in a UOW for the service.
PSTORE	<u>NO</u> IHOTI COLDI	Broker only. Startup value for persistent store.
	WARM	N0 No persistent store.
		HOT Persistent UOWs are restored to prior state during initialization.
		COLD Persistent UOWs are not restored during initialization, and the persistent store is considered empty.
		WARM (Internal Use Only) persistent UOWs are not restored during initialization, but the persistent store remains intact.
UWSTATP	<u>0</u> - 254	Broker: persistent status is maintained either for persistent or non-persistent UOWs.
		Service: persistent status is maintained either for persistent or non-persistent UOWs for a service.
UWTIME	<u>1D</u> <i>n</i> S <i>n</i> M <i>n</i> H <i>n</i> D	Broker: defines the lifetime of a UOW in seconds, minutes, hours or days. This value is the time that it can remain in the system without being completed. If the UOW is not completed within this time, it is deleted with a status of TIMEOUT
		Service: defines the lifetime of a UOW for a service.

Keyword	Value	Description
MAX-UOW-MESSAGE-LENGTH	n <u>31647</u>	Broker: defines the default maximum message size that can be sent.Service: defines the maximum message size that can be sent to a service.
DEFERRED	<u>no</u> I yes	Broker: sets the default DEFERRED attribute for all services.UOWs can be sent to a deferred service even if the service is not registered.Service: sets the DEFERRED attribute for a service.

ACI Fields used for Units of Work

The following fields have been added to the broker ACI control block. Note that the actual field names may differ slightly depending on the programming language being used.

Keyword	Description				
STORE	Indicates whether the specified UOW is persistent or not:				
	0FF The sender accepts the persistence option specified by the service or Broker (this is the default value).				
	BROKER The sender wants persistence.				
	NO The sender does not want persistence, even if the service or Broker default is persistence.				
	Also returned with RECEIVE to indicate if the UOW being received is persistent or not.				
UWTIME	The amount of time that the UOW can remain incomplete without being timed out. This is also referred to as the UOW lifetime.				
STATUS	The current status of a UOW. The status is returned on SEND, RECEIVE, and SYNCPOINT operations. Applicable values are as follows:				
	RECEIVED One or more messages have been sent as part of a UOW but the UOW is not yet committed.				
	ACCEPTED The UOW has been committed by the sender.				
	DELIVERED The UOW is currently being received.				
	BACKEDOUT * The UOW was backed out prior to being committed by the sender.				
	PROCESSED * the receiver of the UOW has committed it.				
	CANCELLED * the receiver of the UOW has cancelled it.				
	TIMEOUT * the UOW was not processed within the specified time.				
	DISCARDED * The UOW was not persistent and its data was discarded over a restart.				
	* The status values marked with an asterisk are persistent, and will only exist for UOWs with persistent status.				

Keyword	Description					
	In addition, the following status values are returned on a RECEIVE operation to indicate if the message being received is part of a UOW or not, and if so, which part:					
	RECV_NONE The message is not part of a UOW.					
	RECV_FIRST The message is the first message in a UOW.					
	RECV_MIDDLE The message is not the first or last message in a UOW.					
	RECV_LAST The message is the last message in a UOW.					
	RECV_ONLY The message is the only message in a UOW.					
	All RECV_values except RECV_NONE reflect an actual UOW status of DELIVERED.					
USTATUS	A user-defined status associated with a UOW. It can be specified as part of a SEND, RECEIVE, or SYNCPOINT operation and will be returned whenever the status of a UOW is queried. See <i>Using User Status</i> below for more information.					
UOWID	A unique identifier for a unit of work. This value is returned on SEND and RECEIVE operations and may be provided on SYNCPOINT operations that are querying status of UOWs.					
UWSTATP	A numeric value indicating the lifetime value for persistent status. This value is a multiplier against the UWTIME value. Applicable values are:					
	0 Use the default specified for the service or broker.					
	1-254 Use 1 to 254 times the UWTIME value as the status lifetime.					
	255 The sender does not want persistent status, even if the service or broker default is persistent status.					

ACI Function SYNCPOINT used for Units of Work

The SYNCPOINT function deals exclusively with UOWs. The following table lists the OPTION values that can be used with the SYNCPOINT function, and the associated behavior and restrictions of each one.

Note: In many cases, the behavior will be different depending on whether the issuer is the sender or the receiver of the UOW.

Option	Caller	Behavior and Restrictions
		If the specified UOW is in RECEIVED status, it will be put into BACKEDOUT status. If persistent status is not specified, no trace of the UOW will remain.
		If the specified UOW is in DELIVERED status, it will be put back into ACCEPTED status and its attempted delivery count will be incremented.
CANCEL		If the specified UOW is in ACCEPTED status, it will be put into CANCELLED status. If persistent status is not specified, no trace of the UOW will remain.
		If the specified UOW is in DELIVERED status, it will be put into CANCELLED status. If persistent status is not specified, no trace of the UOW will remain.

Option	Caller	Behavior and Restrictions	
COMMIT	Sender	If the specified UOW is in RECEIVED status, it will be put into ACCEPTED status. It is now available to be received by the other partner.	
	Receiver	If the specified UOW is in DELIVERED status, it will be put into PROCESSED status. If persistent status is not specified, no trace of the UOW will remain.	
	Both	This is a special case of the COMMIT option, where the caller specifies UOWID=BOTH in the request. This allows the caller to commit two UOWs, one being received and one being sent, in a single atomic operation.	
DELETE	Sender	Deletes the persistent status of the specified UOW. The UOW must be complete and must have been created by the caller. After this request, no trace of the UOW will remain.	
EOC	Sender	Commits the UOW and sets an EOC indication on the associated conversation. See COMMIT for additional information and restrictions.	
EOCCANCEL	Sender	Commits the UOW and sets an EOC-CANCEL indication on the associated conversation. See COMMIT for additional information and restrictions.	
LAST	Sender	Returns the status of the last UOW sent by the caller. In addition, CLASS/SERVER/SERVICE details of the associated server are also returned. The CONV-ID can be included to qualify the request.	
QUERY	Sender	With UOWID=n, returns the status of the specified UOW. In addition, CLASS/SERVER/SERVICE details of the associated server are also returned.	
SETUSTATUS	Both	Updates the user status field of the specified UOW. The UOW must be in RECEIVED, ACCEPTED, or DELIVERED status.	

Options used for UOW Operations

This table lists option values used to support UOW operations:

Option	Function	Behavior and Restrictions
SYNC	SEND	This option indicates that the data being sent is part of a UOW. The UOW is created on the first send, and subsequent sends will add messages to the UOW.
SYNC	RECEIVE	This option indicates that the RECEIVE can be satisfied only with a message in a UOW.
MSG	RECEIVE	This option indicates that the RECEIVE can be satisfied only with non-UOW messages.
ANY	RECEIVE	This option indicates that the RECEIVE can be satisfied by either a non-UOW or a UOW message. It is up to the receiver to determine which, based on the UOWSTATUS field that is returned.
COMMIT	SEND	This option combines a SEND and a SYNCPOINT, OPTION=COMMIT into a single operation. It allows the sender to create and commit a UOW in a single operation.

CID Implementation: Numeric Digits, Characters 0-9 and A-Z

In order to support unique conversation identifiers at Broker restart, there is an implementation of the CID which is alphanumeric and an internal identifier.

Note: The CID is a Broker-generated identifier for the conversation, and the application should not make any assumptions about either the content or format of all or any part of the CID field, or about any relationship between CIDs.

If any of the following three conditions exist, the all-numeric implementation of the CID field will be used in order to ensure compatibility:

- the Broker does not support any UOW processing;
- the application program is using API_VERSION 1 or 2 in its request;

or

the target service does not support UOWs.

Note: This level of compatibility may be removed at some point in the future.

Using Units of Work

- UOW vs non-UOW Conversations
- Use of LOGON and TOKEN
- User Identification for Units of Work
- Which Applications should use UOWs?
- Understanding UOW Status
- UOW Status on RECEIVE
- Using User Status
- Resource and Performance Considerations

UOW vs non-UOW Conversations

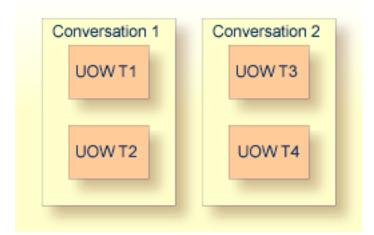

A Broker conversation will support either UOWs or messages, but not both. At the time the conversation is created, the Broker will determine which is to be supported.

Sequencing of Messages across Conversations

The order of delivery of new conversations to receivers is determined by the COMMIT time of the first UOW within its conversation. The conversation delivered to the receiver first is the one containing the first UOW for which the sender issues a SEND,OPTION=COMMIT or SYNCPOINT,OP-TION=COMMIT.

If there is more than one UOW in a conversation, the COMMIT time of the first UOW determines the age of that conversation. Also, multiple UOWs within a conversation are picked up by the receiver, in the same sequence as they were committed by the sender.

Scenario: A server starts to receive UOWs (CONVID=NEW) and receives UOW T1 first, since this UOW is committed first. If the server issues another receive (CONVID=NEW), it receives UOW T3. If, however, the UOWs are not combined in conversations (i.e., every UOW is in a separate conversation), the server receives (CONVID=NEW) UOW T1 first, then UOW T2, UOW T3, etc.

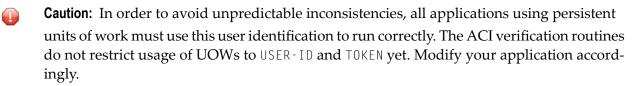

The COMMITTIME field in the Broker control block shows COMMITTIME of the first UOW in a conversation.

Use of LOGON and TOKEN

An explicit LOGON function must be used before a program can use any of the UOW functions. In order to enable client and server programs to recover the status of their UOWs in the event of a failure (Broker, system, or application), these programs must specify a TOKEN value at the time of logon.

User Identification for Units of Work

EntireX Broker identifies participants by ACI fields USER-ID and TOKEN if TOKEN is supplied or by USER-ID and internal ID (so-called physical user ID) if TOKEN is not supplied. However, the implementation of persistent units of work is based on the user identification USER-ID and TOKEN.

Which Applications should use UOWs?

Applications that should consider using UOWs fit into a couple of different categories.

- Applications that currently use multiple messages to communicate a single request are good candidates for UOWs. Grouping these messages within a UOW can give the application additional control over how its data is processed.
- Applications that intend to utilize deferred services, persistence, or persistent status must use UOWs, since these facilities are not available to message-based applications.

Understanding UOW Status

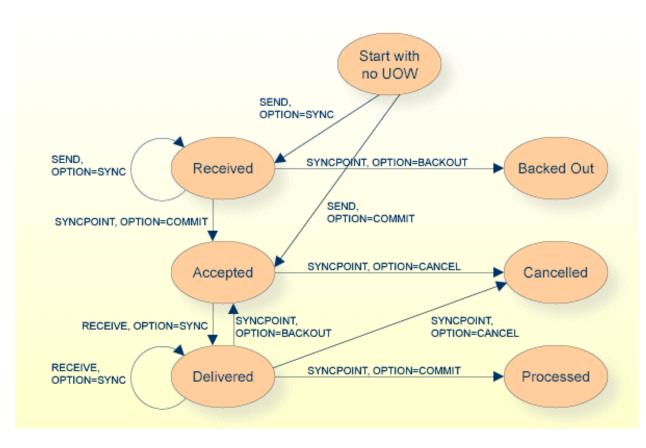

In order to use UOWs effectively, you need to understand

- the meaning of the various UOW status values;
- how they change based on events within the system;

and

how these changes are influenced by both persistence and persistent status.

The diagram below represents the normal status values as a UOW progresses through the system. These statuses and the transitions between them are not affected by either persistence or persistent status. The status values are indicated in ovals.

Normal Status Values as a UOW progresses through System

Note: The UOW is available to be received when it is first committed. The status values BACKEDOUT, CANCELLED and PROCESSED are valid only if there is persistent status.

UOW Status on RECEIVE

When a RECEIVE is issued for a message within a UOW, you might expect that the UOW status returned would be DELIVERED, since this is the actual status of the UOW. This is not the case, however. On a RECEIVE, the Broker returns a special UOW status that reflects additional information about the message and the UOW. These statuses are:

- RECV_FIRST= the message is the first message in a UOW.
- RECV_MIDDLE= the message is not the first or last message in a UOW.
- RECV_LAST= the message is the last message in a UOW.
- RECV_ONLY= the message is the only message in a UOW.
- RECV_NONE= the message is not part of a UOW. This status is particularly useful if the application is receiving both messages and UOWs.

If you receive a status of either RECV_LAST or RECV_ONLY and then issue another RECEIVE for the same UOW, you will get an error 00740301 Conversation found: end of unit of work indicating the end of the UOW.

Using User Status

The user status field of the UOW allows additional, application-specific information to be carried with the UOW. It can be used to maintain status or indicate error information. It can also provide a form of "out-of-band" data communication between the sender and the receiver of a UOW.

For example, if a server is processing a long-running UOW, it can periodically update the user status of the UOW (using SYNCPOINT, OPTION=SETUSTATUS) to indicate its progress. The client can periodically get the user status (using SYNCPOINT, OPTION=QUERY) and report the progress back to the end-user.

As another example, the sender of a long-running UOW can update the user status to indicate that processing of the UOW should be abandoned by the server. The server can periodically get the user status while processing and react accordingly.

Resource and Performance Considerations

Each active UOW consumes memory resources (approximately 140 bytes per UOW) in a preallocated pool, not including the size of the message itself.

Also, additional memory resources such as the conversation and participant control blocks for the UOW, together with messages associated with them, will remain in memory for a deferred service when persistence is used. This can become significant when UOWs are being sent to a deferred service. However, the message itself does not remain in memory if sent to a service which is not currently registered - the whole purpose of deferred services. If the service is currently registered, the message remains in memory.

Messages that are sent to any (registered or unregistered) service can be "paged out" by Broker if storage is required. This feature considerably eases memory consumption when using persistence.

Using Persistence

- When do Persistent UOWs make Sense?
- Adding Persistence to a UOW
- Resource and Performance Considerations
- Which Information is saved with the UOW?
- What happens when Broker restarts?

UOWs and Replicated Servers

When do Persistent UOWs make Sense?

A UOW should be made persistent if the sender wants the Broker to assure that the UOW will be deliverable, even if there is a system or Broker failure. Assured delivery assumes that the intended receiver of the UOW is active, or becomes active within the specified lifetime of the UOW.

Since most existing Broker applications are interactive, they are probably not good candidates for persistent UOWs. New application models can now be implemented, using persistent UOWs. For example, a service that collects information from other services, such as accounting, inventory, logging, etc., would be a good fit for persistent UOWs. Another example could be a client sending a long-running request to a service (one that may be inactive or busy), disconnecting, and coming back some time later to retrieve the results. The reliability of assured delivery makes this model practical.

Persistent UOWs do not require persistent status.

Adding Persistence to a UOW

A UOW can be made persistent:

- by specifying STORE=BROKER in the ACI request that creates the UOW;
- by specifying STORE=BROKER in service definition or service defaults portion of the Broker attribute file, making all UOWs for that service persistent; or
- by specifying STORE=BROKER in the Broker defaults section of the Broker attribute files, making all UOWs in the system persistent.

In addition, specifying STORE=N0 in the ACI request that creates the UOW will explicitly make the UOW non-persistent, overriding any Broker or service default.

Resource and Performance Considerations

A persistent UOW consumes resources in two areas.

- When the UOW is committed by the sender, all of the messages are written to the persistent store. This will generate multiple I/O operations, depending on the number and size of the messages.
- Space used to store the UOW and its messages will be allocated in the persistent store and will remain until the UOW is completed.

Performance of certain specific functions (e.g. SYNCPOINT OPTION=COMMIT by the sender of a UOW) will be affected by the additional time required to perform the I/O operations associated with writing the UOW and message(s) to the persistent store. These operations are performed synchron-

ously because the Broker must ensure that the UOW, once committed, can be recovered in the event of a system or Broker failure.

Which Information is saved with the UOW?

When the UOW is initially created in the persistent store, the following information is written:

- Unit-of-work ID
- Conversation ID
- UOW Sender information, including:
 - User ID
 - Token
 - Server/service/class *
- UOW receiver information, including:
 - User ID **
 - Token **
 - Server/service/class *
- Creation timestamp
- UOW lifetime value
- Persistence and persistent status values

The following pieces of information will be included when the UOW is initially written to the persistent store and will be updated, as needed, during the life of the UOW:

- UOW status
- UOW user status
- Attempted delivery count
- Number of messages in UOW
- Total message size in UOW
- Persistent status lifetime value
- Conversation state and EOC reason code

* Server/service/class information is only saved if the sender or receiver is a registered service.

** The receiver's user ID and token are only saved if the receiver is a service that has already acquired the conversation associated with this UOW. When there are multiple instances of a service, this means that a new conversation can be restarted by any instance of the service, but an existing conversation is bound to a specific instance of the service.

What happens when Broker restarts?

- Restart Behavior of UOW
- Re-creation of Internal Control Blocks
- Behavior of Conversation at Broker Restart

Note: "Restored" is an active UOW which has been returned to ACCEPTED status; "Discarded" is a UOW which has not been returned to ACCEPTED status. "Discarded" does not imply the status of DISCARDED.

Caution: The persistent store must be available before you attempt to restart your Broker; otherwise your Broker will not restart.

Restart Behavior of UOW

Restart Table 1

The behavior during restart of the following states depends on the previous settings of the options Persistent UOW and Persistent Status.

UOW Status	Persistent UOW:	Persistent Status:		UOW Status
before Restart	YES NO	YES NO	and Status	after Restart *
RECEIVED	YES	YES	UOW not restored; Status is restored	BACKEDOUT
RECEIVED	YES	NO	UOW not restored; Status not restored	
RECEIVED	NO	YES	UOW not restored; Status is restored	DISCARDED
RECEIVED	NO	NO	UOW not restored; Status not restored	
ACCEPTED	YES	YES	UOW is restored; Status is restored	ACCEPTED
ACCEPTED	YES	NO	UOW is restored; Status is restored	ACCEPTED
ACCEPTED	NO	YES	UOW not restored; Status is restored	DISCARDED
ACCEPTED	NO	NO	UOW not restored; Status not restored	
DELIVERED	YES	YES	UOW is restored; Status is restored	ACCEPTED
DELIVERED	YES	NO	UOW is restored; Status is restored	ACCEPTED
DELIVERED	NO	YES	UOW not restored; Status is restored	DISCARDED

UOW Status before Restart	Persistent UOW: YES NO	Persistent Status: YES NO	Behavior of UOW and Status	UOW Status after Restart *
DELIVERED	NO	NO	UOW not restored; Status not restored	
PROCESSED **	YES	YES	Status is restored	PROCESSED
PROCESSED **	YES	NO	Status is not restored	
PROCESSED **	NO	YES	Status is restored	PROCESSED
PROCESSED **	NO	NO	Status not restored	

* If either UOW or its status is restored.

** In this state, the UOW information has already been deleted upon reaching PROCESSED status.

Restart Table 2

The behavior during restart of the following states does not depend on the settings of Persistent UOW; in these cases only the Persistent Status exists and does not change after a restart. There is no UOW to be restored.

UOW Status before Restart	Behavior of Status	UOW Status after Restart
CANCELLED	Status is restored	CANCELLED
DISCARDED	Status is restored	DISCARDED
BACKEDOUT	Status is restored	BACKEDOUT
TIMEDOUT	Status is restored	TIMEDOUT

Re-creation of Internal Control Blocks

To restore a UOW, the Broker re-creates all internal control blocks necessary to represent the UOW when it was accepted. The table displays the targets of each control block type:

Control Block Type	Association: Sender Receiver	Notes
РСВ	Sender; Receiver (optional)	PCB = Participant CB
SCB	Sender; Receiver	SCB = Service CB
ССВ	Sender; Receiver	CCB = Conversation CB
		Two CCBs represent the conversation.
UWCB	Receiver	UWCB = unit of work CB
		The UWCB represents the UOW.

Note: The messages associated with the UOW are not re-created in memory until a RECEIVE is actually issued for the UOW.

Behavior of Conversation at Broker Restart

Broker sets any units of work (UOWs) that are in DELIVERED status to ACCEPTED status during restart processing. If this is the first unit of work within a conversation sent by a client to a server, the assignment of the conversation to a particular server is dropped and the conversation is again available for all servers offering the same service.

If there is more than one unit of work in a single conversation and the first UOW is already received and committed by the server, the link to the server will kept even after this (non-first) UOW has reverted from DELIVERED to ACCEPTED status during restart processing. The server can retrieve units of work after restart with function RECEIVE OPTION=SYNC, CONVID=ANY and will get all old conversations containing UOWs first and then new conversations containing UOWs.

Servers performing a RECEIVE OPTION=SYNC, CONVID=NEW will retrieve only conversations not already assigned to this server. We strongly recommend that you implement RECEIVE OPTION=SYNC, CONVID=ANY or CONVID=OLD to retrieve already assigned conversations.

UOWs and Replicated Servers

Special consideration must be given when restarts occur, and there are persistent UOWs that are being sent to replicated servers, e.g. when more than one copy of a server is active. This is because a UOW is not associated with a server instance until the UOW's conversation is actually received by a server. From an application perspective, this means that a conversation that has not yet been received by its target server will be restored so that any instance of the server can process it. However, once the conversation has been received, any subsequent UOWs sent on the conversation will be restored so that only the specific instance, based on USER-ID and TOKEN, can receive them. The reasoning behind this is that a broker restart can occur without the servers being restarted, and the servers could be maintaining context information based on the conversation.

It is important to note that this can cause problems if the server instances are started as a result of load and the same load conditions are not present after the restart. For example, a UOW could be bound to the fifth instance of a server, but after a restart there is only enough load to start three instances. For this reason, we recommend that replicated servers using persistent UOWs not maintain any conversations with multiple UOWs.

Using Persistent Status

- When does Persistent Status make Sense?
- Adding Persistent Status to a UOW

Resource and Performance Considerations

When does Persistent Status make Sense?

Persistent status should be considered for applications in which the sender needs to know if UOWs were actually processed successfully. In cases where the data associated with a UOW can be easily re-created in the event of a failure, persistent status may be a more desirable and lower-overhead alternative to a persistent UOW.

Persistent status does not require a persistent UOW.

Adding Persistent Status to a UOW

A UOW's status can be made persistent:

- by specifying a UWSTATP value between 1 and 254 in the ACI request that creates the UOW;
- by specifying a UWSTATP value between 1 and 254 in service definition or service defaults portion of the Broker attribute file, making the status of all UOWs for that service persistent; or
- by specifying a UWSTATP value between 1 and 254 in the Broker defaults section of the Broker attribute files, making the status of all UOWs in the system persistent.

Specifying UWSTATP=255 in the ACI request that creates the UOW will explicitly make the UOW status non-persistent, overriding any broker or service default.

Resource and Performance Considerations

Using persistent status consumes resources in two areas.

- The persistent store is updated each time the UOW is modified, by either the sender or the receiver. These modifications occur whenever a SEND or RECEIVE function is issued for the UOW, or whenever its status is changed, such as by SYNCPOINT OPTION=COMMIT. Depending on the implementation, this will generate one or more I/O operations.
- The space used for the UOW (but not its messages) in the persistent store remains allocated for some period of time after the UOW has been completed.

The performance of individual requests will generally be affected by the additional time required to perform the I/O operations associated with maintaining persistent status. At this time, all operations are performed synchronously, although that may change in future releases.

Recovery Processing

- Introduction
- Determining the Status of a UOW
- A Real-world Example: Chess-by-Mail

Introduction

UOWs and persistence provide functionality for the application program (either client or server) to recover from failures: i.e., system, broker or application. In addition, this functionality allow new types of applications to be built, including ones not requiring concurrent execution of the client and server.

There are no standard rules for recovery, because each application model will use this functionality differently and will have different requirements for recovery. But the considerations in the following section should be kept in mind.

Determining the Status of a UOW

The most useful function for recovery is the SYNCPOINT, OPTION=LAST. This function will return the UOWID, CID, and status of the last UOW created by the caller, based on the USER-ID and TOKEN. This function can be used when an application starts or when it detects a failure to determine how much processing has been completed on a UOW. This information can then be used to decide how to recover from the failure.

A Real-world Example: Chess-by-Mail

Chess-by-mail is a sample of an application that takes advantage of UOWs, persistence, and persistent status. In generic terms, this application involves a client and a server exchanging messages on a single conversation. The conversation is long-running, and there is no requirement that the client and the server be active at the same time.

Although chess-by-mail was conceived as a single application, it is perhaps easier to describe its operation separately for the client and the server side. By convention, the white player is the client and the black player is the server. For simplicity, any user interaction has been left out of the description. Also for simplicity, only one chess-by-mail game is assumed to be running at any one time.

- Client Behavior
- Server Behavior

Client Behavior

The behavior of the chess-by-mail client is as follows:

- 1. Logon, specifying a USER-ID and TOKEN, which allow recovery of prior UOWs.
- 2. Issue SYNCPOINT, OPTION=LAST to determine the status of the last UOW created.
- 3. If the return code is 00780305 UOW not found, then there is no game in progress. So send the first white move to the server with: SEND OPTION=COMMIT,CID=NEW. If the send is successful, logoff and exit.
- 4. If the return code from SYNCPOINT is 0, then there is a last UOW and therefore a game is in progress. The UOW status value is examined to decide how to proceed.
- 5. If the status is ACCEPTED, then the server has not yet received the last move, so logoff and exit.
- 6. If the status is DELIVERED, then the server is currently processing the last move, so logoff and exit.
- 7. If the status is TIMEOUT, then the server did not receive the last move before its lifetime expired, so logoff and exit.
- 8. If the status is PROCESSED, then the server has received the last move and committed the UOW. Our application model has the client sending a move in response and committing both UOWs at the same time. So we need to receive the new move and send a reply to it.
- 9. Get the server's move with RECEIVE, OPTION=SYNC, CID=*n*, where *n* is the CID returned from SYNCPOINT OPTION=LAST.
- 10. Send the response move back using SEND OPTION=SYNC, CID=n.
- **11.** Commit both the received and sent UOWs with a single call SYNCPOINT OPTION=COMMIT, UOWID=BOTH.
- 12. Logoff and exit.

Server Behavior

The behavior of the chess-by-mail server is as follows:

- 1. Logon, specifying a Userid and Token, which allow recovery of prior UOWs.
- 2. Register as the chess-by-mail server.
- 3. Issue SYNCPOINT OPTION=LAST to determine the status of the last UOW created.
- 4. If the return code is 00780305 UOW not found, then there is no game in progress. So we receive first white move from the client with: RECEIVE OPTION=SYNC, CID=NEW. When the RECEIVE has been completed, continue at step 11.
- 5. If the return code from SYNCPOINT is 0, then there is a last UOW and therefore a game is in progress. The UOW status value is examined to decide how to proceed.
- 6. If the status is ACCEPTED, then the client has not yet received the last move, so deregister, logoff and exit.
- 7. If the status is DELIVERED, then the client is currently processing the last move, so deregister, logoff and exit.
- 8. If the status is TIMEOUT, then the client did not receive the last move before its lifetime expired, so deregister, logoff and exit.
- 9. If the status is PROCESSED, then the client has received the last move and committed the UOW. Our application model has the server sending a move in response and committing both UOWs at the same time. So we need to receive the new move and send a reply to it.
- 10. Get the client's move with RECEIVE, OPTION=SYNC, CID=*n*, where *n* is the CID returned from

SYNCPOINT, OPTION=LAST.

- **11.** Send the response move back using SEND, OPTION=SYNC, CID=*n*.
- 12 Commit both the received and sent UOWs with a single call:

SYNCPOINT, OPTION=COMMIT, UOWID=BOTH.

13. Deregister, logoff and exit.

7 Broker UOW Status Transition

Initial UOW Status: NULL Received	144
Initial UOW Status: Accepted Delivered	
Initial UOW Status: Processed Timedout	146
Initial UOW Status: Cancelled Discarded Backedout	147
Legend for UOW Status Transition Table	148

8 Data Compression in EntireX Broker

Introduction	150
zlib	150
Implementation	150
Sequencing Summary	151
Sample Programs	

Data compression within EntireX Broker allows you to exchange smaller packet sizes between clients and servers. This helps to reduce response time during transmissions as well as improve the overall network throughput, especially with low-bandwidth connections.

This chapter gives an overview of data compression in EntireX Broker.

See also: COMPRESSLEVEL under Broker ACI Fields | Data Compression under Writing Applications: Client and Server | Publish and Subscribe in the ACI Programming documentation.

Introduction

Compression is performed only on the SEND and RECEIVE buffers. The client or server application has the option of setting the level of compression/decompression for data transmission. The compression level can be set to achieve either no compression or a range of compression/decompression. If during a data transmission the data buffer does not compress, a logged warning message 00200450 indicates that the data has not been compressed during transmission.

Note: The compression level is used to control compression only between the application and the Broker kernel.

zlib

zlib is a general-purpose software implementing data compression across a variety of platforms. Version 1.1.4 of zlib is implemented starting with EntireX Broker version 7. The functions used within EntireX Broker represent a subset of those available within the zlib software.

The compression algorithms are implemented through the open source software zlib.

Implementation

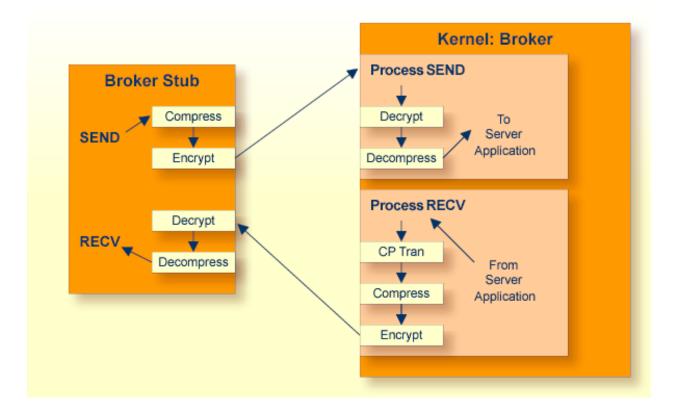

Compression of the data is implemented by the following components of EntireX:

Components	Description			
Broker control block		ntains a field that is used to set the compression ND/RECEIVE transmission whether the data sed. Possible values:		
	0 - 9	0 = no compression, 9 = maximum compression/decompression		
	N	Default. No compression.		

Components	Description
	Y Compression level 6
	If the data buffer does not compress, the kernel or stub generates a logged warning message 00200450 indicating that the transmitted data is not compressed.
	Note: See also ACI control block field COMPRESSLEVEL.
Stubs: Broker stub and Java stub	The behavior of the Broker stub and Java stub is identical with respect to compression.
	The logic of a client or server application sets the compress level of the Broker control block when it issues the SEND or RECEIVE command. If the application issues a SEND, the stub compresses the data buffer before transmission of the data. If the application issues a RECEIVE, the stub decompresses the data buffer after reception of the data. Note: The compression level is used to control compression only between the application
	and the Broker kernel.
Broker kernel	When a client or server application SENDs the data to the Broker kernel, the application specifies the level at which the kernel is to decompress the data.
	When the client or server application issues the RECEIVE command, the Broker kernel compresses the data before returning it to the application. The application specifies the level at which the kernel is to compress the data.

Sequencing Summary

The following graphic shows the sequencing of data compression within EntireX Broker:

Sample Programs

convClt and convSrv

Sample programs convClt and convSrv in directory *examples*/ACI/conversational/C can be used as an example of performing compression/decompression. Using the -rn option will cause compression to be used at level $\langle n \rangle$.

convSrv can be instructed to use compression/decompression by specifying, for example:

convSrv -7 -r4

- r4: This will cause a compression/decompression level of 4 to be used on all transmissions between the server and the Broker.
- -7: The -7 that is needed as compression/decompression is only supported at Version 7 or above.

convClt can be instructed to use compression/decompression by specifying, for example:

convClt -7 -r2

- •r2: This will cause a compression/decompression level of 2 to be used on all transmissions between the client and the Broker.
- -7: The -7 that is needed as compression/decompression is only supported at Version 7 or above.

Option -g<filename>convClt and convSrv

To test how well various types of data will compress, you can use the option <code>-g<filename></code>. You can use, for example, the following syntax to specify that input is to be extracted from a pre-existing file, using the two arguments from above.

convClt -7 -r2 -gmyfile1.txt

This will read in *myfile1.txt* and send it to a registered server. If convSrv is the server, convSrv will reverse the data sequence and return the data.

convSrv -7 -r4 -gmyfile2.txt

This will write in *myfile2.txt* the data sent from the client.

Accounting in EntireX Broker

EntireX Accounting Data Fields	156
Using Accounting under UNIX and Windows	159
Using Accounting under z/OS	160
Example Uses of Accounting Data	162

This chapter describes the accounting records for Broker that can be used for several purposes, including:

- application chargeback for apportioning EntireX resource consumption on the conversation and/or the application level;
- performance measurement for analyzing application throughput (bytes, messages, etc.) to determine overall performance;
- trend analysis for using data to determine periods of heavy and/or light resource and/or application usage.

EntireX Accounting Data Fields

In the EntireX Accounting record, there are various types of data available for consumption by applications that process the accounting data:

Field Name	Accounting Version	Type of Field	Description
SMF Record Type	1	1-byte unsigned integer	z/OS only.Type of SMF record.
Record Write Time	1	UNIX, Windows, BS2000/OSD and z/VSE: A14 Timestamp in "YYYYMMDDHHMMSS" format z/OS: Timestamp	UNIX, Windows, BS2000/OSD and z/VSE: The time this record was written to the accounting file in YYYYMMDDHHMMSS format z/OS: SMF timestamp.
SMF system ID	1	4-byte string	z/OS only.ID of the SMF system.
SMF subsystem ID	1	4-byte string	z/OS only.ID of the SMF subsystem.
EntireX Broker ID	1	A32	Broker ID from attribute file.
EntireX Version	1	A8	Version information, <i>v</i> . <i>r</i> . <i>s</i> . <i>p</i> where <i>v</i> =version <i>r</i> =release <i>s</i> =service pack <i>p</i> =patch level for example 9.6.0.00.
Platform of Operation	1	A32	Platform where EntireX is running.
EntireX Start Time	1	A14 Timestamp in "YYYYMMDDHHMMSS" format	Time EntireX was initialized in YYYYMMDDHHMMSS format.

Field Name	Accounting Version	Type of Field	Description
Accounting Record Type	1	A1	It is always C for conversation. Future Types will have a different value in this field.
Client User ID	1	A32	USER-ID ACI field from the client in the conversation.
Client Token	1	A32	TOKEN field from the ACI from the client.
Client Physical ID	1	A56	The physical user ID of the client, set by EntireX.
Client Communication Type	1	I1	Communication used by client: 1 = Net-Work 2 = TCP/IP 3 = APPC 4 = WebSphere MQ 5 = SSL
Client Requests Made	1	I4	Number of Requests made by client.
Client Sent Bytes	1	I4	Number of bytes sent by client.
Client Received Bytes	1	I4	Number of bytes received by client.
Client Sent Messages	1	I4	Number of messages sent by client.
Client Received Messages	1	I4	Number of messages received by client.
Client Sent UOWs	1	I4	Number of UOWs sent by client.
Client UOWs Received	1	I4	Number of UOWs received by client.
Client Completion Code	1	I4	Completion code client received when conversation ended.
Server User ID	1	A32	USER-ID ACI field from the server in the conversation.
Server Token	1	A32	TOKEN field from the ACI from the server.
Server Physical ID	1	A56	The physical user ID of the server, set by EntireX.
Server Communication Type	1	I1	Communication used by Server: 1 = Entire Net-Work 2 = TCP/IP 3 = APPC 4 = WebSphere MQ 5 = SSL
Server Requests Made	1	I4	Number of requests made by server.
Server Sent Bytes	1	I4	Number of bytes sent by server.

Field Name	Accounting Version	Type of Field	Description
Server Received Bytes	1	I4	Number of bytes received by server.
Server Sent Messages	1	I4	Number of messages sent by server.
Server Received Messages	1	I4	Number of messages received by server.
Server Sent UOWs	1	I4	Number of UOWs sent by server.
Server Received UOWs	1	I4	Number of UOWs received by server.
Server Completion Code	1	I4	Completion code server received when conversation ended.
Conversation ID	1	A16	CONV-ID from ACI.
Server Class	1	A32	SERVER-CLASS from ACI.
Server Name	1	A32	SERVER-NAME from ACI.
Service Name	1	A32	SERVICE from ACI.
CID=NONE Indicator	1	A1	Will be N if CONV - ID=NONE is indicated in application.
Restarted Indicator	1	A1	Will be R if a conversation was restarted after a Broker shutdown.
Conversation Start Time	1	A14 Timestamp in "YYYYMMDDHHMMSS" format	Time conversation began in YYYYMMDDHHMMSS format.
Conversation End Time	1	A14 Timestamp in "YYYYMMDDHHMMSS" format	Time conversation was cleaned up in YYYYMMDDHHMMSS format.
Conversation CPU Time	1	I4	Number of microseconds of CPU time used by the conversation
Client Security Identity	2	A32	Actual identity of client derived from authenticated user ID.
Client Application Node	2	A32	Node name of machine where client application executes.
Client Application Type	2	A8	Stub type used by client application.
Client Application Name	2	A64	Name of the executable that called the broker. Corresponds to the Broker Information Service field <i>APPLICATION-NAME</i> in the ACI Programming documentation.
Client Credentials Type	2	I1	Mechanism by which authentication is performed for client.
Server Security Identity	2	A32	Actual identity of server derived from authenticated user ID.
Server Application Node	2	A32	Node name of machine where server application executes.

Field Name	Accounting Version	Type of Field	Description
Server Application Type	2	A8	Stub type used by server application.
Server Application Name	2	A64	Name of the executable that called the broker. Corresponds to the Broker Information Service field APPLICATION - NAME in the ACI Programming documentation.
Server Credentials Type	2	I1	Mechanism by which authentication is performed for server.
Client RPC Library	3	A128	RPC library referenced by client when sending the only/first request message of the conversation.
Client RPC Program	3	A128	RPC Program referenced by client when sending the only/first request message of the conversation.
Server RPC Library	3	A128	RPC library referenced by server when sending the only/first response message of the conversation.
Server RPC Program	3	A128	RPC Program referenced by server when sending the only/first response message of the conversation.
Client IPv4 Address	4	A16	IPv4 address of the client.
Server IPv4 Address	4	A16	IPv4 address of the server.
Client Application Version	4	A16	Application version of the client.
Server Application Version	4	A16	Application version of the server.
Client IPv6 Address	5	A46	IPv6 address of the client.
Server IPv6 Address	5	A46	IPv6 address of the server.

Note: Accounting fields of any version greater than 1 are created only if the attribute AC-COUNTING-VERSION value is greater than or equal to the corresponding version. For example: accounting fields of version 2 are visible only if ACCOUNTING-VERSION=2 or higher is specified.

Using Accounting under UNIX and Windows

Broker Attribute File Settings

Retrieving Accounting Data

Broker Attribute File Settings

ACCOUNTING = NO | YES | (YES, SEPARATOR=Separator Characters) (Default is NO)

Set this parameter to "NO" (i.e., do not create accounting data) or "YES" to create accounting data. Up to seven separator characters can specified using the SEPARATOR suboption, for example ACCOUNTING = (YES, SEPARATOR=;). If no separator character is specified, the comma character will be used.

Retrieving Accounting Data

The accounting file will be located in the Broker's installed directory. The file's name is based on the ETB_LOG environment variable and the current date and time (for uniqueness). Example: If ETB_LOG is set to BROKER1.LOG, the accounting data file will be named BROKER1_YYYMMDDH-HMMSS.csv. If ETB_LOG is not set, the Broker's ID will be used, with an extension of CSV (e.g. ETB048_YYYYMMDDHHMMSS.csv). See *Environment Variables in EntireX*.

Using Accounting under z/OS

The ACCOUNTING attribute indicates if accounting records will be generated. Accounting records are written upon successful completion of a conversation. A conversation ending in an application error (such as a timeout) is considered to be a successful conversation.

- Attribute File
- Retrieving Accounting Records
- Accounting Record Layouts
- Notes

Attribute File

ACCOUNTING={NO|128-255}

Set this parameter to "NO" (i.e., do not create accounting records) or to a number between 128 and 255, which specifies the SMF record type to use when writing the accounting records. In order to avoid conflicts with other applications that also produce SMF records, check with your z/OS systems programmer for an appropriate number. In addition, check with your z/OS systems programmer to ensure that the selected SMF record number is set up to be written.

Default value: NO

Retrieving Accounting Records

The standard IBM IFASMFDP utility program may be used to selectively offload Broker and Broker Services SMF records. Analysis and report routines - either user-written or those available from IBM or various software vendors - may subsequently be used to process the offloaded records.

```
//* Copies selected records from the "live" SMF data sets
//*
//* Replace nnn (OUTDD parameter) with a valid SMF record type
//*
//* Note: the "DISPLAY SMF" operator command will show the names of the
//* SMF data sets
//*
//IFASMFDP EXEC PGM=IFASMFDP
//SYSPRINT DD SYSOUT=*
//MAN1 DD DISP=SHR,DSN=SYS1.MAN1
//MAN2 DD DISP=SHR,DSN=SYS1.MAN2
//MAN3 DD DISP=SHR,DSN=SYS1.MAN3
//OUTPUT DD DISP=(MOD,CATLG).
// UNIT=SYSDA,SPACE=(TRK,(15,15),RLSE),
// DCB=(RECFM=VBS,LRECL=32760,BLKSIZE=0),
// DSN=EXX.SMF.RECORDS
//SYSIN DD *
 DATE(2002001,2099366)
 START(0000)
 END(2359)
 INDD(MAN1,OPTIONS(DUMP))
 INDD(MAN2,OPTIONS(DUMP))
 INDD(MAN3,OPTIONS(DUMP))
 OUTDD(OUTPUT.TYPE(nnn))
//*
```

Note: The IBM publication *MVS System Management Facilities* (*SMF*) provides complete information on SMF.

Accounting Record Layouts

EntireX provides three mappings for its accounting records in the following members, all located in the EXX960.SRCE data set:

- EXXCACT A C language include file that maps the accounting record;
- EXXACTR An Assembler language MACRO that will generate a DSECT of the accounting record;
- EXXSACT An SAS DATA step that will read in a file with the appropriate field names.

Notes

- Since there is no server for Broker Command and Information Services, no server data is generated in the SMF records for Command and Information Services conversations.
- The unit for CPUTIME is expressed in microseconds.

Example Uses of Accounting Data

- Chargeback
- Trend Analysis
- Tuning for Application Performance

Chargeback

Customers can use the EntireX accounting data to perform chargeback calculations for resource utilization in a data center. Suppose EntireX Broker is being used to dispatch messages for three business departments: Accounts Receivable, Accounts Payable, and Inventory. At the end of each month, the customer needs to determine how much of the operation and maintenance cost of EntireX Broker should be assigned to these departments. For a typical month, assume the following is true:

Department	Amount of Data	Percentage	Messages Sent	Percentage	Average Percentage
Accts Payable	50 MB	25	4000	20	22.5
Accts Receivable	40 MB	20	6000	30	25
Inventory	110 MB	55	10000	50	52.5

The use of Broker resources here is based upon both the amount of traffic sent to the Broker (bytes) as well as how often the Broker is called (messages). The average of the two percentages is used to internally bill the departments, so 52.5% of the cost of running EntireX Broker would be paid by the Inventory Department, 25% by the Accounts Receivable Department, and 22.5% by the Accounts Payable Department.

Trend Analysis

The Accounting Data can also be used for trend analysis. Suppose a customer has several pointof-sale systems in several stores throughout the United States that are tied into the corporate inventory database with EntireX. The stubs would be running at the stores, and the sales data would be transmitted to the Broker, which would hand it off to the appropriate departments in inventory. If these departments wish to ascertain when the stores are busiest, they can use the accounting data to monitor store transactions. Assume all of the stores are open every day from 9 AM to 10 PM.

Local Time	Average: Weekday Transactions per Store	Maximum Weekday Transactions in any Store	Average Weekend Transactions per Store	Maximum Weekend Transactions in any Store
9 AM	7.3	27	28.2	83
10 AM	11.2	31	29.3	102
11 AM	14.6	48	37.9	113
12 noon	56.2	106	34.8	98
1 PM	25.6	65	34.2	95
2 PM	17.2	52	38.5	102
3 PM	12.1	23	42.7	99
4 PM	18.3	34	43.2	88
5 PM	26.2	47	45.2	93
6 PM	38.2	87	40.6	105
7 PM	29.6	83	39.2	110
8 PM	18.6	78	28.6	85
9 PM	11.2	55	17.5	62

The owner of the stores can examine the data and make decisions based upon the data here. For example, on weekdays, he or she can see that there is little business until lunchtime, when the number of transactions increase. It then decreases during lunch hour; then there is another increase from 5 PM to 8 PM, after people leave work. Based on this data, the owner might investigate changing the store hours on weekdays to 10 AM to 9 PM. On the weekend the trends are different, and the store hours could be adjusted as well, although there is a more regular customer flow each hour on the weekends.

Tuning for Application Performance

Assume that a customer has two applications that perform basic request/response messaging for similar sized messages. The applications consist of many Windows PC clients and Natural RPC Servers on UNIX. An analysis of the accounting data shows the following:

Application Type	Class	Server			Average Client Messages Received per Conversation
Application 1:	CLASS1	SERVER1	SERVICE1	10.30	10.29
Application 2:	CLASS2	SERVER2	SERVICE2	10.30	8.98

A further analysis of the accounting data reveals that there are a lot of non-zero response codes in the records pertaining to Application 2, and that a lot of these non-zero responses indicate timeouts. With that information, the customer can address the problem by modifying the server code, or by adjusting the timeout parameters for SERVER2 so that it can have more time to get a response from the Service.

10 Timeout Considerations for EntireX Broker

Timeout Units	166
Timeout Settings	166
Relationship between Timeout Values	167
Timeout-related Error Messages	169

This chapter describes the timeout settings for EntireX Broker.

Timeout Units

The timeout duration can be specified in seconds (S), minutes (M) or hours (H), for example 100M. If no unit is specified, the default is seconds.

Timeout Settings

Timeout Setting	Description
Client Non-activity Timeout	Any broker stub application that issues a LOGON but does not issue a REGISTER is a client. During logon, broker allocates resources to each client and keeps them available to the client until the client application issues a LOGOFF. A client is considered inactive when it is not issuing a broker request. A typical example of a broker request by a client is the SEND function.
	The CLIENT-NONACT value defines the maximum period of time a client can remain inactive. See CLIENT-NONACT under <i>Broker Attributes</i> in the platform-independent administration documentation. If the client continues to be inactive beyond this period of time, Broker releases all the resources allocated to this client. This time is a global attribute, applicable to all clients of the Broker.
Server Non-activity Timeout	Any broker stub application that issues a LOGON and also issues a REGISTER is a server. During logon and registration, broker allocates resources to each server, and keeps them available to the server until the server issues a DEREGISTER and LOGOFF. A server is considered inactive when it is not issuing a broker request. A typical example of a Broker request by a server is the RECEIVE function.
	The SERVER-NONACT value defines the maximum period of time a server can remain inactive. See SERVER-NONACT under <i>Broker Attributes</i> in the platform-independent administration documentation. If the server continues to be inactive beyond this period of time, Broker releases all the resources allocated to this server. This time is a per-service attribute, and can vary from one service definition to another. All servers, registered to the same service, inherit the same SERVER-NONACT time. If a server registers to more than one service, the highest SERVER-NONACT value is taken as the non-activity time period.
Conversation Non-activity Timeout	A conversation begins when a client successfully sends a message addressed to a server. The Broker allocates a unique conversation, even before the server receives this message. Broker also allocates resources to manage each conversation. A conversation remains active as long as messages are being exchanged with this conversation ID. The conversation remains inactive as long as neither a client nor a server makes a Broker request, referencing this conversation ID. The resources allocated to a conversation are freed when either a client or a server issues E0C.

Timeout Setting	Description
	The CONV-NONACT value defines the maximum period of time a conversation can remain inactive. If the conversation continues to be inactive beyond this period of time, Broker releases all the resources allocated to this conversation.
UOW Lifetime (UWTIME)	Each UOW has a lifetime value associated with it. This is the time that a UOW is allowed to exist without being completed. A UOW is completed when it is successfully
	either cancelled or backed out by its sender
	• or cancelled or committed by its receiver.
	If a UOW is in ACCEPTED status when this lifetime expires, the UOW is placed into a timeout status. Lifetime timeouts will not occur when the UOW is in either RECEIVED or DELIVERED status. See CONV-NONACT description in <i>Relationship between Timeout Values</i> .
Transport	If Entire Net-Work is used to transmit a Broker request, the setting of the Entire Net-Work
Timeouts	NODE statement parameter REPLYTIM may influence the behavior of the application (see your Entire Net-Work documentation for details). All non-activity timeouts in the Broker configuration should be considered when determining the maximum time. This maximum time should be less than the value defined for REPLYTIM in the Entire Net-Work configuration.

Relationship between Timeout Values

The interdependency between different timeouts is described as follows:

UOW Messages

Non-UOW Messages

UOW Messages

	UWTIME	
CLIENT-NONACT		SERV-NONACT
	CONV-NONACT	г

- A server or a client engaged in a conversation will not be timed out until the UOW that they are handling times out. CLIENT-NONACT (or SERV-NONACT) has no effect if it is shorter than UWTIME.
- A conversation may time out earlier than either the client or the server. When an existing conversation times out, the participating server and client can start a new conversation. We recommend you set the CONV-NONACT shorter than CLIENT-NONACT (or SERV-NONACT).
- If either the client or server times out before the conversation does, the conversation does not continue, that is, it reaches end of conversation (EOC). Nevertheless, the surviving participant (client or server) can continue and receive any unread messages.
- When a conversation times out, Broker checks for the status of all UOWs in this conversation. Any UOW with status RECEIVED or DELIVERED is backed out and enters into ACCEPTED status. "Accepted" means that the UOW can be received by anyone (with CONV-ID=NEW), and that the conversation has lost the link to the consumer of the UOW.

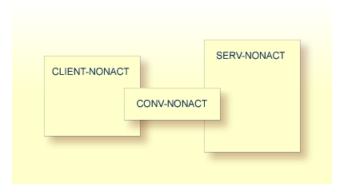

A common relationship between these three timeout values is as follows, although this may not be the optimum combination in all situations:

UWTIME > SERV - NONACT > CLIENT - NONACT > CONV - NONACT

In common situations, this combination will achieve optimal resource consumption without recourse to repeatedly restarting applications.

Non-UOW Messages

Timeout behavior remains the same as in UOW messages, except that UWTIME (UOW lifetime attribute) is not applicable here. The optimal hierarchy between the three timeout values is shown below:

SERV-NONACT > CLIENT-NONACT > CONV-NONACT

Timeout-related Error Messages

When any client or server or conversation times out, the Broker does not immediately notify the application. The application receives notification when it makes its next Broker request. The following are the error messages commonly associated with the respective timeouts. The errors listed below can occur in the case of blocked and non-blocked ACI calls. A blocked call is one in which the ACI field WAIT is set to either "YES" or a non-zero numeric value.

See message 00740074.

- CLIENT-NONACT
- SERV-NONACT
- CONV-NONACT

• Special Case for UOW Messages

CLIENT-NONACT

In the following errors, it is assumed that client only has timed out, while the server and conversation are active.

Error Number	Error Text	Explanation
00020002	User does not exist	When the timed out client tries to make a Broker request.
00030012	partner	The surviving partner (server) receives this error when attempting to receive on a conversation which is closed because the client has timed out. If there are any unread messages, the server successfully receives them.

SERV-NONACT

In the following errors, it is assumed that only the server has timed out, while the client and conversation are active.

Error Number	Error Text	Explanation
00020002	User does not exist	When the timed out client tries to make a Broker request.
00030067		The surviving partner (client) receives this error when attempting to send on a conversation which is closed because the server timed out.

CONV-NONACT

It is assumed that server and client are active.

Error Number	Error Text	Explanation
	No matching conversation found	When either a server or a client attempts a new Broker request affecting this timed out conversation.
00030073	Conversation timeout occurred	When both client and server are already engaged in a conversation, and the conversation time out without the partner issuing any Broker request.

Special Case for UOW Messages

UOWs involved in a conversation, and which are in DELIVERED state, revert to ACCEPTED state when the conversation times out. UOWs in ACCEPTED state are no longer bound to a server nor to an existing conversation. Therefore, UOW in ACCEPTED state is part of a new conversation that is available to any server.

11 EXXMSG - Command-line Tool for Displaying Error Messages

EXXMSG is a command-line tool that displays the text of an EntireX error message for a supplied error number. It is available on all platforms.

Running the EXXMSG Command-line Utility

Under z/OS, command-line utility EXXMSG is located in library EXB960.LOAD. Under UNIX and Windows, the utility is located in the EntireX *bin* directory.

Command-line Parameters

The only command-line parameter is any 8-digit error code.

Sample Command

exxmsg 02150148

Sample Output

Software AG webMethods EntireX 9.0.0 (473) Linux 3.1.10-1.16-desktop (c) Copyright 1997 - 2012 Software AG. All rights reserved.

02150148 EntireX Broker not active : (or Transport-Specific Error Text) Explanation The requested Broker specified in BROKER-ID is not reachable. Action Check the BROKER-ID. If it is correct, check if ETB_TRANSPORT environment variable is defined and if defined, it should point to the desired transport method. If problem persists, contact your network administrator.
